Enterprise and High-Performance Computing Under Your Control

Appro is **leading 4P x86 computing** by combining the latest technology that meets the demands of the enterprise HPC market.

4-Way XtremeWorkstation™

- AMD Opteron™ 8000 Series processors
- Up to 128GB of DDR2 533/667 memory
- Up to 6.0TB SATA or 2.4TB SAS
- Hot-swappable drives
- 2 PCI-E x16 slots for high-end graphics card
- Windows® or Linux OS

4-Way 3U XtremeServer™

- AMD Opteron™ 8000 Series processors
- Up to 128GB of DDR2 533/667 memory
- Up to 4.5TB SATA or 1.8TB SAS
- 2 PCI-E x16 and 3 PCI-X slots
- Hot-swappable drives
- Redundant power supplies & fans
- ServerDome Management – IPMI 2.0
- Windows® or Linux OS

For more information, please visit www.appro.com
or call Appro Sales at 800-927-5464

AMD Opteron™
Processors:

- Quad-Core Ready - increase capacity without altering datacenter infrastructure
- Best performance per-watt with energy-efficient DDR2
- Optimized system performance with Direct Connect Architecture

Manage Any Data Center. Anytime. Anywhere.

Avocent builds hardware and software to access, manage and control any IT asset in your data center, online or offline, keeping it, and your business, "always on".

Agility.

With Coyote Point, you'll never have to wonder if your network is fast enough or flexible enough. You'll know it is.

From local to global load balancing, application acceleration or ultimate network manageability, Coyote Point leads the pack. We take the guesswork and difficulty out of application traffic management. You won't find anything faster, smarter or more affordable.

Find out why more than 2,000 businesses rely on us to maximize their infrastructure. Learn what Coyote Point could mean to your Web and network traffic.

Write info@coyotepoint.com or call 1-877-367-2696.

**Coyotes respond with lightning speed.
Your network should, too.**

HIGH-PERFORMANCE COMPUTING

The power of Linux clusters and high-performance computing is undeniable, and we've got numbers to prove it. We also show you how to create a high-availability solution with Red Hat Enterprise Linux. Don't have a roomful of computers handy? You can still leverage the HPC capabilities of Linux by using distcc to distribute your compile tasks across the few computers you happen to have running.

As always, there's much more. How well do you think Ubuntu installer will do when put through a usability test? We've got the results. Who needs a PIM when you've got Emacs? We'll show you how to make this editor keep you organized.

Power of **32** Processors

256 GB of Memory

Based on industry leading AMD Opteron™ microprocessors, the **HPC A5808-32** server provides industry leading scalable x64 processing with the latest I/O, network, memory, and power efficient technologies.

With features such as **AMD quad-core Opteron™** microprocessors and up to 256GB of DDR2 for memory-intensive performance, multithreaded applications like CRM, ERP, e-commerce, and virtualization will see significant performance improvements.

And **HPC MasterSight™** delivers features to help manage the system with inclusive diagnostic tools.

Specializing in High Performance Computers, HPC systems, Inc. is a solution provider serving the financial, health, educational, and government sector. We appreciate that you have a choice of dozens of vendors, but not all of them have our uncompromising dedication and experience in producing the best solutions.

Inaccurate Items in Magnatune Article

I have to raise an objection (or five) to the Magnatune article in the August 2007 *Linux Journal*.

First, Apple's iTunes uses AAC, the same audio codec for DVDs you get off the shelf. This codec is much tighter in compression but has better audio quality than MP3.

Second, DRM'd iTunes music is encoded at 128kbps using AAC. A buck a song at 128kbps sounds rather decent.

Third, EMI's non-DRM'd music will sell for \$1.29, but it will be double the encoding rate, 256kbps, so it will sound much better. This doubling of the bandwidth (which I doubt will all be used) will make the files pulled bigger, and thus the extra cost is justifiable.

Fourth, the non-DRM'd music is still encoded in AAC format and possibly wrapped in an MPEG-4 container. It won't be MP3'd; it won't be WMA'd—both for Apple's legal eye will require licensing the codec. Plus, iPods can't listen to Ogg Vorbis files either. Apple hasn't thought about putting in the free (as in freedom) codec in the iPod's firmware as well as QuickTime.

Fifth, EMI's music catalog isn't all DRM-free yet.

Apparently, the person who wrote the article forgot to do his research. I believe the keynotes of the past WWDC and MacWorld conferences should help. They're still up on iTunes as podcasts for free (as in beer).

--
Kelly "STRedWolf" Price

Sold on Kubuntu

Being a UNIX/Linux user for more than 30 years and seeing the evolution of computers has been very interesting. First, we had large pieces of iron on raised floors and huge air conditioning bills and large support staff, and we all carried large boxes of cards for the larger programs.

I got my PhD in Astrophysics in 1972, and my dissertation required more than \$1,000,000 in computer time on a CDC 7600 and then later on a Cray 1S. It was taking 3.5 hours per case for simulation of light transport in real planetary atmospheres. Now I can do a case in less than ten minutes on an AMD64. I still wonder if people fully realize just how much compute power they have at their fingertips.

I wrote a book in 1978, and in Chapter 1, I wrote that I had figured out what the human race was doing overall. We are trying to get all of human knowledge at the fingertips of every man, woman and child on the planet. We are about to get there.

Back to your article [Nicholas Petreley's "Amazing Free Distributions Abound", July 2007]. I used SUSE for years and years. But last year, I was converted to Kubuntu, and with 7.04, there is no way I can ever go to another distro. It has, with all the official repositories, given me access to more programs and utilities than I'll ever need.

Last year, I developed a short Intro to Linux course for free adult training centers and continuing education facilities. I use Kubuntu 7.04 because of the live CD and the ease of installation. I also use a cheap Airlink USB Wi-Fi critter for \$10 on sale at

Fry's Electronics that plugs and plays without intervention by the owner and really, really helps get things going.

I am working on getting freshmen high-school students to start up on Linux. Think about it. They would never have to buy another piece of software for the rest of their high-school and college careers. They'd have every compiler they ever would need. They would have OpenOffice.org for their reports and spreadsheets, and LaTeX for engineers and mathematicians for any mathematics they encounter. The list goes on and on.

I developed and taught all the courses at Silicon Graphics until I retired 12 years ago, when SGI started downhill. So, I guess it's still in my blood to continue the fight against ignorance. "Push back the frontiers of ignorance" was my motto as a prof and instructor. Get a thought to go where no thought has gone before.

Keep up the good work.

--
Chuck Adams

Don't Bogart That Link, My Friend

In the Tech Tips column in the July 2007 issue, a method to prevent services from starting is described for those who do not want to use the graphical interfaces. However, there is a specific command-line tool available just for that task, `chkconfig`. I think this tool works even better than crowding the `/etc/rc[0-6].d` directories with unclear links.

From the `chkconfig` man page: "`chkconfig` provides a simple command-line tool for maintaining the `/etc/rc[0-6].d` directory hierarchy by relieving system administrators of the task of directly manipulating the numerous symbolic links in those directories."

To follow the example in the magazine, instead of renaming `S25bluetooth` to `s25bluetooth`, simply type `chkconfig bluetooth off` (and `chkconfig bluetooth on` to turn it back on again).

KEEP YOUR BUSINESS RUNNING SMOOTHLY

PROTECT YOUR SMALL BUSINESS WITH THE BUILT-IN SECURITY ENHANCEMENTS OF THE DUAL-CORE INTEL® XEON® PROCESSOR IN YOUR SERVERSDIRECT SYSTEM.

SDR-1105T 1U ENTRY LEVEL SERVER

\$959.99

EXCELLENT GENERAL PURPOSE SERVER FOR ORGANIZATIONS WITH THE NEED FOR A LOW, ENTRY LEVEL PRICE

- * 1U Rackmount Chassis with 520W power supply
- * Supermicro X7DVL-L Server Board with Intel® 5000V (Blackford VS) Chipset
- * Intel® Dual-Core Xeon Processor 5050 3.0GHZ 667 MHz
- * Total 512MB, 2pcs x 256MB Kingston DDR2 533Mhz FB-DIMM ECC
- * Seagate SATAII 80GB 7200 RPM 8MB Cache SATA 3.0Gb/s Hard Drive
- * 4 x 1" Hot-swap SATA Drive Bays
- * Two Intel® 82563EB Dual-port Gigabit Ethernet Controller
- * Intel® ESB2 SATA 3.0Gbps Controller RAID 0, 1, 5, 10 support

STARTING PRICE \$1,199

SDR-2503T 2U APPLICATION SERVER

Highest performing with Dual Core/ Quad Core Xeon CPU based. Excellent with general purpose applications and provide the most power.

- * 2U Rackmount Chassis with 650W power supply
- * Supermicro X7DVL-E Server Board with Intel® 5000V (Blackford VS) Chipset
- * Intel® Dual-Core Xeon Processor 5050 3.0GHZ 667 MHz
- * Total 512MB, 2pcs x 256MB Kingston DDR2 533Mhz FB-DIMM ECC
- * Seagate SATAII 250GB 7200 RPM 8MB Cache SATA 3.0Gb/s Hard Drive
- * 6 x 1" Hot-swap SATA Drive Bays
- * Intel® (ESB2/Gilgal) 82563EB Dual-port Gigabit Ethernet Controller
- * Intel® ESB2 SATA 3.0Gbps Controller RAID 0, 1, 5, 10 support

STARTING PRICE \$2,199

SDR-3500T 3U DATABASE SERVER

Easily Scalable storage solution with hot-swap functionality for growing businesses

- * 3U Rackmount chassis with Redundant 800W power supply
- * Supermicro X7DBE+ Server Board with Intel® 5000P (Blackford) Chipset
- * Intel Quad-Core Xeon Processor E5310 1.6GHZ
- * Total 1024MB, 2pcs x 512MB Kingston DDR2 533MHz FB-DIMM ECC
- * Seagate SATAII 500GB 7200 RPM 16MB Cache SATA 3.0Gb/s Hard Drive
- * 16 x 1" Hot-swap SATA Drive Bays
- * Dual-port Gigabit Ethernet Controller
- * Intel ESB2 SATA 3.0Gbps Controller RAID 0, 1, 10 support

STARTING PRICE \$1,999

SDR-7045B-TB 4U FILE SERVER

4U Quad-Core Xeon Server offers excellent value and expandability

- * 4U Rackmountable / Tower with 650W power supply
- * Supermicro Super X7DBE Server Board with Intel® 5000P (Blackford) Chipset
- * Intel Quad-Core Xeon Processor E5310 1.6GHZ
- * Total 1024MB, 2pcs x 512MB Kingston DDR2 667MHz FB-DIMM ECC
- * Seagate SATAII 750GB 7200 RPM 16MB Cache SATA 3.0Gb/s Hard Drive
- * 6 x 3.5" Hot-swap SAS/SATA Drive Bays
- * Dual-port Gigabit Ethernet Controller
- * Intel ESB2 SATA 3.0Gbps Controller RAID 0, 1, 5, 10 support

STARTING PRICE \$3,299

SDR-5111T 5U ADVANCED STORAGE SERVER

Quad Core dual Xeon CPU based, with 24 hot-swap hard disk bays suitable for 18TB of pure data Storage capacity

- * 5U Rackmount chassis with Redundant 1350W power supply
- * Supermicro X7DBE Server Board with Intel® 5000P (Blackford) Chipset
- * Intel Quad-Core Xeon Processor E5310 1.6GHZ
- * Total 1024MB, 2pcs x 512MB Kingston DDR2 667MHz FB-DIMM ECC
- * Seagate 750GB 7200 RPM 16MB Cache SATA 3.0Gb/s Hard Drive
- * 24 x 1" Hot-swap Drive Bays
- * Intel® (ESB2/Gilgal) 82563EB Dual-port Gigabit Ethernet Controller
- * Intel ESB2 SATA 3.0Gbps Controller RAID 0, 1, 5, 10 support

Don't Short Python

It's a little late to be writing about the June 2007 issue, but I just reread the Lua article, and I'm a bit disappointed, so I thought I'd write.

In general, it seems to be a pretty good introduction to Lua. However, the author did a lot of comparing to Python, and I think that comparison was done unfairly. Whenever such a language article is written, it really should be reviewed by an expert in the language it's being compared to. The author is clearly not very experienced with Python, and it shows.

Lua has a key advantage for its intended purpose (its impressively small size), but people should select it for its real advantages, not because of mistaken impressions. In general, it looks to me like many of Lua's traits make it quite unsuitable for large programs, which is fine, as it's not intended for that. However, Python is pretty darn suitable for both large and small.

Chris

More Ruby on Rails

I have really been digging *Linux Journal* ever since I subscribed to your fine publication. Lately, I've been enjoying the shell scripting articles, and in the July 2007 issue, the article on vector graphics was rather interesting. In the future, I think you guys should do some more articles on Ruby and Ruby on Rails. I really enjoyed the one edition almost completely dedicated to Ruby. It would really tickle my fancy if you put some more Linux Web-development-related things into the magazine. Anyway, keep up the good work with making my favorite Linux publication.

--
Patrick

No SOP Here, Move Along

As a developer of embedded systems, including Linux, for the past two decades, I was very interested in the article "Standard Operating Procedures for Embedded Linux Systems" [August 2007].

The article seems to describe a limited approach to embedded Linux development and certainly not an "SOP".

The primary software described, buildroot, is a terrific and powerful tool for embedded developers, as are many packages from uclibc.com; however, such high-level tools come with limitations. Buildroot, for example, is heavily entwined with the uClibc library, which is not a viable choice for every system. The "five standard procedures" violate basic design methodology by selecting the hardware first. Once all packages are selected, only then can a tool like buildroot be considered; only amateurs select the tools before determining the task.

The article appropriately focuses on reducing memory and storage requirements, but no mention is made of alternate compressed filesystems, Flash filesystems and especially the new xip (execute in place) file support. Understanding the limitations of the space-saving software, such as uClibc and BusyBox, requires deep knowledge but is ignored in this article. Using packages that are not designed for cross-build is very difficult, despite the article's statement that it sometimes makes good sense to build these packages on the target. Bootup and shutdown time is important for many embedded systems, and this has design implications regarding hardware and software but isn't mentioned. Often, some new kernel feature is required, but upgrading the kernel may not be possible (many BSPs are dropped or rendered nonfunctional in time), so devising a solution is difficult, which is not addressed.

I wish we could download a tool, run a configurator and have a functional image pop out, trim a little "fat", install and ship, but life is rarely so simple. It's a nice article on one group's basic development process, but there is nothing standard here. "One size fits all" isn't yet a viable approach for embedded Linux.

WHAT'S NEW IN KERNEL DEVELOPMENT

only closed-source drivers, so Ondrej had to hack into the data flow itself and do his own analysis in order to understand how to interact with the hardware.

There's a new performance monitoring tool on the block. **Mark Seger** has been coding and tweaking his **collectl tool** (collectl.sf.net) for about four years, and he finally has decided to release it under a free software license. It tracks a whole bunch of system stats and displays them in various formats. Mark has invited everyone to use it, abuse it and send him bug reports. Although because it already has been in use on his personal system for years, it probably is quite robust and stable.

Intel's coming out with some new **IOMMU hardware**, aka **Virtualization Technology for Directed I/O**, and **Anil S. Keshavamurthy** has posted a patch to support that hardware in Linux. There is still some question as to whether the code is quite ready to be integrated into the kernel—**Andrew Morton** thinks it might be too slow—but overall, Anil's work has received plenty of support, and it is excellent to see Intel being so proactive in supporting its hardware.

Chris Mason has been working on **BTRFS** (BTree filesystem), a new effort aimed at data integrity. As **Albert D. Cahalan** said during the discussion following Chris's announcement, storage hardware can't really be trusted, so filesystems have to take up the slack and make sure users' data doesn't get lost. BTRFS seems

Ondrej Zary has produced a new free software driver to support **IRTouchSystems touchscreens**. The manufacturer releases

to be finding a lot of support among kernel developers; however, it's still in the early stages and shouldn't be used for any kind of production environment yet. One of Chris' main ideas is to keep data integrity support simple, even if it means not implementing fancier features that may be popular among other filesystems.

Every once in a while someone decides to dig out one of the particularly ugly parts of the kernel and fix it up nice. **Nick Piggin** has done that recently with the **buffer layer**. This is the part of the kernel that deals with block devices, tracking a variety of data, including the status of writes to particular disk blocks. Nick's replacement, **fsblock**, is a much cleaner, shinier implementation. Among other improvements, fsblock's support for large block sizes is much simpler and nicer than what was there before. His code also avoids the deadlocks common to the existing version. But, although these and many other improvements definitely are great, fsblock is still in the early stages of development, and folks like **Jeff Garzik** are concerned that other aspects of the buffer-layer problem space may force fsblock's code into nastier and more tangled knots. So far, the only filesystem Nick has ported to use fsblock has been **Minix**, a famously simple and academic filesystem intended for student consumption. The more complicated journaling filesystems, such as ext3/4 and ReiserFS, will be the real test. And, even if fsblock eventually does rise to that challenge, developers like **Christoph Hellwig** don't think Nick's improvements are significant enough to justify replacing the whole buffer layer and porting all that filesystem code.

USER FRIENDLY by J.D. "Hliad" Frazer

THE PROBLEM IS THAT XINE SEEMS TO PLAY IT BACK ALL CHOPPY AND STUFF.

LINUX JOURNAL EDITION

Expert Included.

Tim is dedicated to processes that make every server from Silicon Mechanics a model of consistency and reliability. The build and quality processes he applies guarantee that your server arrives ready to perform.

He likes servers that combine outstanding performance with long-term value. The Rackform nServ A411 is impressive because it's a compute cluster in one rack unit, with four Dual-Core AMD Opteron™ 8000 Series processors and 16 DDR2 DIMM sockets. The Direct Connect Architecture allows all eight cores to work together with maximum efficiency. Tim knows that the 4 Dual-Core Second-Generation processors are designed to offer seamless upgradeability to Quad-Core.

When you partner with Silicon Mechanics, you get more than a powerful AMD server—you get an expert like Tim.

They Said It

When something that was originally scarce starts becoming abundant, something strange happens. You find that you start making money *because of* that thing rather than *with* that thing. That's the Because Effect.

—JP Rangaswami, British Telecom, confusedofcalcutta.com/2007/07/08/prince-ly-returns-from-the-because-effect

Non-open-source users typically use price as a factor in their decisions. They think that a more expensive computer will be faster, more sturdy, and will last longer. That's not necessarily true. It is definitely not true in software, and it is becoming less true in hardware....We believe that all our other worthy goals (such as gaining market share for Linux) will be accomplished best by a myopic, utterly self-absorbed focus on solid hardware and honest customer support.

—Cathy Malmrose, CEO, ZaReason, Inc., allaboutubuntu.wordpress.com/2007/06/26/zareasons-ceo/#more-62

Today Gates openly concedes that tolerating piracy turned out to be Microsoft's best long-term strategy. That's why Windows is used on an estimated 90% of China's 120 million PCs. "It's easier for our software to compete with Linux when there's piracy than when there's not", Gates says. "Are you kidding? You can get the real thing, and you get the same price." Indeed, in China's back alleys, Linux often costs more than Windows because it requires more disks. And Microsoft's own prices have dropped so low it now sells a \$3 package of Windows and Office to students.

—David Kirkpatrick, in *Fortune*, money.cnn.com/magazines/fortune/fortune_archive/2007/07/23/100134488/index.htm

Bottom line—this was an oversight, pure and simple.

—Dell spokesperson, on why the Linux-equipped Inspiron 1420s at first appeared to cost more than Vista-equipped ones, www.desktoplinux.com/news/NS9933912441.html

It's clear that a shift away from Windows began about two years ago, and the data show that this migration is now accelerating. Linux has benefited, but we also see corresponding growth in niche operating systems for nontraditional client devices. The landscape is changing.

—John Andrews, Evans Data Corp., www.evansdata.com/press/viewRelease.php?pressID=51

None of this technology is optimally applied to getting laid.

Ten Questions for Sean Moss-Pultz

When iPhone launched in late June 2007, *Newsweek* snarked, "Not since Moses parted the Red Sea has anything this miraculous appeared on earth. Will it cure cancer?" Meanwhile, the OpenMoko Project has been hard at work providing earth with a Linux-based cure for iPhone.

We've covered OpenMoko a number of times already, but all were before iPhone parted the seas of mainstream ink otherwise being spilled on war, politics and Paris Hilton coverage. So, we interrupted the overbooked time of Sean Moss-Pultz, Program Manager of OpenMoko, to probe his thinking about OpenMoko in a post-iPhone world.

LJ: First, can you give us a point-by-point comparison of OpenMoko with iPhone?

SM-P: You can check this out: wiki.openmoko.org/wiki/IPhone.

LJ: But really, OpenMoko is not an "open-source alternative" to iPhone?

SM-P: No, not even close. We're in a totally different market. The last thing on earth I want to do is start copying the iPhone—no offense to Apple. They've built a beautiful product, but do we really need another closed, locked-down phone?

Fundamentally, we're totally different. End-user Freedom is our passion. Apple is about giving you an incredibly polished experience—exactly how they want you to have it. End users really have no freedom. They cannot change the device if they don't like the way Apple chooses to make things. OpenMoko is the anti-iPhone.

LJ: So, you're pro-FOSS?

SM-P: The entire OpenMoko system and application software are built using free and

open-source software (FOSS).

On the system side, OpenMoko uses software with a tireless history of success and stability, such as the Linux kernel, the GNU C library, the X Window System and the GTK+ toolkit, to name only a few. OpenMoko is Mobile FOSS.

Apple won't even give you an SDK for the iPhone.

We give you *everything* for Free—exactly the same tools that we use internally. We want you to change this device—personalize away to your heart's content.

I like to describe OpenMoko as a movement to create an open platform that empowers people to personalize their phones, much like computers, in any way they see fit.

Apple makes sure their entire software stack stays closed. We chose to make the entire software stack open. From a control standpoint—the things corporations love—this borders on insanity. But, I think by pushing these borders, we will let loose the possibility for immense innovation.

Innovation, in my opinion, is seldom found within the endless cubicles of a large corporation. Most commonly, it manifests itself within the intense focus and concentration that all individuals seem to have access to when they stare at a single problem long enough.

Staying with a problem long after most would quit is a luxury few companies can afford. Instead, I want to focus on the fundamentals—the framework—to use a more specific term. This includes the following parts:

- UI—common look and feel for end users.
- Data—common storage model for applications.

- Libraries—common platform for developers.

We believe these are some of the key areas to solidify for innovation to form. And, we believe this will benefit not just my company (FIC), but everyone who uses a mobile phone.

We really try to make things as easy as possible for developers. Software-wise, our platform is still in the early stages, but things are moving fast. It's an incredibly exciting time for us now.

LJ: Does OpenMoko see verticals as the key to breaking open the twin silos of phone makers and carriers? If so, which ones? You mention "major corporations, Fortune 500s, hospitals, real estate, engineering, the arts...." Is OpenMoko downstream with any of those? How?

SM-P: Enterprise is a very interesting vertical market for us now. I can't mention exactly whom we're talking with currently, but it's all the big names. If you think about this, it makes total sense. They have huge IT budgets and the ability to put scores of people working on custom solutions. More and more they also are running GNU/Linux on the server. So, having another client (besides cumbersome PCs) makes for quite a value proposition.

LJ: Here's why we ask. Steve Jobs said the iPhone is closed to developers at Cingular's (now AT&T's) request. Companies like AT&T generally don't like open phones. Yet, we have evidence that phone makers and carriers will both open up and make exceptions for big vertical buys.

SM-P: Yeah, I think this will be a huge

ZaReason It's Good

In the last couple issues' UpFront sections, we've followed Dell's toe-dipping into the surging demand for Linux-based laptops and desktops. It's important, however, to look at the other end of the corporate scale for gear sources as well. EmperorLinux and LinuxCertified are two familiar standouts there. A new one starting to get attention is ZaReason, Inc., in Berkeley, California.

ZaReason grew out of family volunteer work at the Alameda

Computer Recycling Center (see the *LJ* Index this month for some interesting stats about the ACRC) and crafts cheap, high-quality machines, intended mostly for hands-on techies. "Typically, we ship to longtime Linux activists who want fully open-source machines, but do not have the time to research components and configurations", says the company's About page.

Check 'em out: www.zareason.com/shop/home.php.

—DOC SEARLS

market. I mean, most everyone I know in business uses company phones. Why not let the company personalize the phone for its employees?

LJ: Who are the early developers, exactly?

SM-P: Hackers, developers, technologies, hobbyists...students, really, we've seen so many people it's mind-boggling. I'm totally blown away by the sheer volume of interest we are getting now.

This is quite a pleasant surprise. Sure, we thought an open phone would shake things up a bit. But this is more like an earthquake.

LJ: What are we seeing in pickup from different parts of the world?

SM-P: Well, I would say it's still mainly a western thing. Europe and the US represent most of the e-mails. But, South America, Africa and Asia now are really starting to pick up pace. It's really getting global!

LJ: Jonathan Schwartz of Sun showed off an OpenMoko phone, no? What more is coming of that?

SM-P: Yeah, that was our Neo. I really can't make any more comments than that now. Sorry.

LJ: How do you see the open-phone market developing? In what ways will it resemble and/or differ from the "white box" computer market in which Linux grew?

SM-P: Oh, great question. I think the market will be quite different. In the embedded system world, there is just a tighter level of integration between hardware and software.

LJ: What about other phone uses, such as camera, texting, audio (for example, podcast) recording and music/video playback?

SM-P: We need to open the mobile ecosystem. A mobile phone has the potential to be a platform that can do anything that a small computer with broadband access can do.

For the people pushing this project, an open phone is not really even a product. It's the very embodiment of our vision of technology. We absolutely, passionately, believe that something as fundamental to our lives as the mobile phone must be open.

—DOC SEARLS

Your World Runs Faster With c-tree® Database Technology

A small footprint c-tree database controls the traffic lights on your way to work.

Packages are scanned and delivered using a scalable c-tree database that can run on handheld devices and mainframes.

A high throughput c-tree database validates your credit card transactions.

Your financial transactions are secure because they are authenticated using a c-tree database.

Your digital pictures are well-organized thanks to the transparent deployment of a c-tree database within your photo album software.

Your world runs faster (and you sleep better!) with c-tree database technology.

FairCom provides high performance, low maintenance data management technology. Our customers – ranging from small startups to multinational corporations – are able to overcome application-specific performance dilemmas because c-tree gives them precise control over their database operations. Super-charge your application and simplify your deployment! Download an evaluation edition of c-tree today.

A Ticket out of Poverty

Looking beyond the walls of our temporary office in Nairobi, Kenya, one can see fences with barbed wire and security guards near any building audacious enough to show a sign of wealth. Everything seems brown here, from the dust on the roads and in the air to the rusty tin roofs protecting most residents from the sun and rain. We are in Kibera—with an estimated 1.5 million residents, it is the largest slum in Africa.

Our project is unconventional, for not only do we avoid hiring security guards, we also were invited by the youth within the community. We find ourselves here to run a media development project, powered by open-source software. We avoided most travel warnings and, to some, left our common sense at the border when we chose to bring laptops and digital cameras to one of the poorest areas in the world. Many residents in Kibera live on a few dollars a day, grappling problems like HIV/AIDS and malnutrition, and have never used a computer before. When we arrived, however, we were greeted by quick-learning youth interested in trying new technologies and media tools to improve their lives and the state of their entire community.

This is the second such project that Five Minutes to Midnight (FMM, www.fiveminutestomidnight.org), a youth-led organization from Canada, is running. Initially started to promote youth involvement in human rights through media and journalism, FMM launched the Article 13 Initiative (A13I, www.a13i.org) in December 2005 to promote the use of open-source software in media projects in developing countries. Its pilot project took place that December and the following January in N'Djamena, Chad, one of the poorest countries in the world.

With a base operating system of Fedora Core and packages, such as The GIMP, Inkscape and OpenOffice.org, the project began through a partnership with *Rafigui*, Chad's only national youth-led newspaper. It provided technical training to a dozen youth with the aim of helping sustain the *Rafigui* newspaper. The project was a resounding success, with follow-up workshops taking place in Burkina Faso in January 2006 and *Rafigui* now planning its own open-source software-focused workshops for the near future.

Now, in July 2007, FMM is finishing a new set of workshops in Kenya with a local

organization called Shining Hope for the Community (SHOFCO). Working with 20 youth from Kibera, the seven-week project focuses on training in open-source software and journalism, as well as exploring how Web 2.0 tools can be used within international development. The seeds of the project were planted informally almost a year ago, when SHOFCO received a small grant to purchase a printer and received an Ubuntu CD in the mail. The printer helped them start the first community-run newsletter in Kibera, while the CD instilled a sense of technical curiosity in the youth. Even today, a year later, we get requests to teach some of the young people how to use Ubuntu.

One of the biggest advantages of open-source software and using or creating openly available resources is that such projects easily can be initiated by others. What is surprising is that such projects can end up

costing very little and have incredibly fast results. If driven by a motivated organization, the projects often can be sustained long past the initial workshops and have an immense potential to help many people.

How to Run a Media Development Project Using Open-Source Software

The best piece of advice for starting such a workshop is to be flexible, open-minded and to think critically about the work being done. Such questioning should focus on everything from the general idea of using open-source software to specifics, such as which printer drivers to include on a resource CD. Even the

idea of using open-source software was not a trivial one when initially planning workshops in Chad. The specific tasks of newspaper creation—text editing, layout design, photo editing and illustration—are well supported by open-source software packages, such as OpenOffice.org, Scribus, GIMP and Inkscape, but the same may not be true for tasks related to video production or animation.

Technical questions are but a small subset of the ones you will need to answer, and most questions are difficult to fathom or predict. Traveling from a wealthy country to a relatively poor one comes with many challenges surrounding power structures and stereotypes. An illustrative example comes from a former workshop participant, who warned his teachers that students will stay silent, smile and then nod out of respect for the instructor, even if they do not understand a single word.

Teaching anything about computers to new users is not easy, and the difficulty is compounded when students only have a basic level of literacy or the language of instruction is not their first language. A typical response to such challenges is localization. Indeed, one of the advantages of using open-source software is the ability to customize user interfaces, either by modifying labels or going the extra mile and re-inventing entire user interfaces. Although many Linux distributions sport numerous languages, incorporating them into lessons is controversial at best.

The linguistic history of Africa, like any other continent, is complex, and many languages tend to be oral ones, with either no written versions or ones that are barely taught in schools. For example, Swahili is very popular as a spoken language in Kenya, but most people learn to read and write in English in schools in Kibera. Working in Swahili is seen as substandard to English, even if it is conversationally easier. A further problem is that although the operating system may be localized, the likelihood that every package within it is also localized is small, especially if the language being considered is not mainstream. Even with apparently French packages, some help files would say, "To be translated" (in English), causing a great deal of confusion to French-speaking students in Chad.

No matter how difficult the software or seemingly ineffective the lesson plans, most students are happy to be given an

opportunity to acquire technical training and will, in fact, learn a great deal. We have noticed this regardless of operating system, be it Fedora Core or Windows, or whether we're teaching programming in Java or text editing in OpenOffice.org. The most important aspect of the technical plan should be its simplicity in terms of maintenance and sustainability. Indeed, if you make sure that the computers function long after you are gone and are well stocked with tutorials and books providing instructions on software packages, there's a good chance students will go out of their way to learn what's available—just make sure your local partnering organization provides the security to store those resources and gives your workshop participants the ability to access them.

In this sense, it is often best to avoid complex software or hardware configurations. For our work, we often prefer laptops—they're cheap to transport, have only one plug and use battery power when electricity is unavailable (which can be a major problem in Chad and Kenya). We also avoid

setting up complex network configurations or user accounts, unless this is something we can teach within the workshops themselves.

Conclusion

Even if the workshops go well and you end your multiweek experience in bliss, there's often one difficulty creeping about: practical applications. All effort is for naught if, at the end of the weeks, there is no longer-term plan for how the software will be used to improve the organization or start new projects. At the beginning of this article, I mentioned the importance of focusing workshops around a project and how FMM works specifically with organizations interested in printed media. In this case, we often make a newspaper issue based on workshops and assume the lessons learned will be used to improve the newspaper. In some cases, the benefits may be more direct, such as helping participants get job offers to move beyond the poverty that has plagued their lives. In many cases, there are no easy answers

to questions raised about planning a media development project. Indeed, international development is fraught with ethical issues and cultural challenges. One of the most difficult aspects of such work is that although a project may last several weeks, the end result is the teacher leaving and returning to a lavish lifestyle, while the participants may remain in impoverished areas for years to come, if not their entire lives. Nevertheless, such projects are worthwhile because they bring hope to the communities they focus on, and instructors and organizers often gain unforgettable friendships and experiences. So, the next time you have a vacation or a few weeks free, consider getting involved in such a project. In such cases, open source is more than a software paradigm—it is a ticket out of poverty.

—WOJCIECH GRYC

Expert Included.

Forrest and the Product Development team never stop thinking about the problems facing today's IT administrators. Power efficiency, compute density, green computing, reliability, and serviceability are just some of the things he makes a priority. That's why Forrest is excited about the new Bladeform 8100 Series Blade Server Platform.

With support for multiple Quad-Core Intel® Xeon® Processors 5300 Series, the Bladeform 8100 takes advantage of Intel's proven reliability and energy efficiency. Forrest is very impressed that the Bladeform 8100 provides 90%+ high-efficiency redundant power supplies for operating cost reduction and earth-friendly computing. Up to ten blades, each with 2 removable hard drives, can be installed in the 7U enclosure, allowing 60 total blades in a 42U rack. The Bladeform 8100 is a perfect choice for mission-critical enterprise applications, scale-out, and high performance computing environments.

When you partner with Silicon Mechanics, you get more than a powerful Intel-based Solution—you get an expert like Forrest.

Silicon Mechanics and the Silicon Mechanics logo are registered trademarks of Silicon Mechanics, Inc. Intel, the Intel logo, Xeon, and Xeon Inside are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.

Spice up man pages, perform keyword searches, and create a logo or mix audio at the command line.

>> Colorize man Pages

Linux man pages are an integral part of Linux folklore. Even seasoned users have to refer to man pages every once in a while. Wouldn't it be much more fun if man pages were a little colorful? If you run a graphical X desktop, it isn't much trouble to add some color to the otherwise very technical and curt manuals. Simply copy the contents of the file called XTerm in the app-defaults directory to your .Xdefaults file. The following replaces the .Xdefaults file entirely:

```
$ cp /usr/share/X11/app-defaults/XTerm ~/.Xdefaults
```

Edit the file and uncomment these lines (or create them if they aren't in your particular file). Change the colors from yellow and red to your favorite colors if yellow and red do not suit you:

```
*VT100*colorULMode: on
*VT100*colorUL: yellow
!*VT100*italicULMode: on
*VT100*underLine: off
! Uncomment this to use color for the bold attribute
*VT100*colorBDMode: on
*VT100*colorBD: red
```

Enjoy the colorful man pages!
—Girish Venkatachalam

>> Keyword Search in Firefox

Firefox is a great browser, but you already knew that, right? Firefox's keywords facility can be used for a neat search trick. It is best used for a directed search engine that digs specific data—for example, a Bugzilla search, IMDb search, LXR search or Marcel/wine search (www.wine-searcher.com), and so on. Here are the steps:

1. Go to a site that offers a simple search facility (for example, IMDb, LXR or your local Bugzilla).
2. Place the cursor within the search box.
3. Right-click, and select Add a Keyword for this Search.
4. Give your new search shortcut a name.
5. Give your new search shortcut a short keyword (for example, I use bz for my Bugzilla search and lxr for LXR).

That's it.

To try out your new keyword search shortcut, open a new tab

(Ctrl-T), place the cursor at the location bar (Ctrl-L), type your keyword followed by the search term(s)—for example, assuming you added keyword bz for the search at bugzilla.mozilla.org, then typing bz 95849 in the location bar will show you this: https://bugzilla.mozilla.org/show_bug.cgi?id=95849.

This is an ideal way to use a search engine that digs through some specific data.

—Steve Fernandez

>> Command-Line Logo

You can create a neat logo from the Linux command line:

```
$ convert -size 800x120 xc:white -font Times-Roman
-pointsize 100 -fill gray -annotate +20+80 'Linux is cool!'
-fill black -annotate +23+83 'Linux is cool!' -trim
+repage logo.png
```

And, the following command should display the result:

```
$ qiv logo.png
```

If you want to play with multiple colors and fonts, the following will help:

```
$ convert -list type
$ convert -list color
```

—Girish Venkatachalam

>> Combine Audio Files at the Command Line

Say you have two PCM audio files in WAV format. You can concatenate them with the following command (they must both have the same sample rates, encoding, endianness and so on):

```
$ sox file1.wav file2.wav combined.wav
```

If you want to mix two audio tracks, try this:

```
$ soxmix file1.wav file2.wav mix.wav
```

—Girish Venkatachalam

Linux Journal pays \$100 for tech tips we publish. Send tips and your contact information to techtips@linuxjournal.com.

EmperorLinux

...where Linux & laptops converge

Portable

Since 1999, EmperorLinux has provided pre-installed Linux laptops to universities, corporations, government labs, and individual Linux enthusiasts. Our laptops range from full-featured ultra-portables to desktop replacements. All systems come with one year of Linux technical support by phone and e-mail, and full manufacturers' warranties apply.

Toucan T61/T61ws

ThinkPad T61/T61ws by Lenovo

- Up to 15.4" WSXGA+ w/ X@1680x1050
- NVidia Quadro NVS 140M graphics
- 1.8–2.4 GHz Core 2 Duo
- 512 MB–4 GB RAM
- 80–160 GB hard drive
- CDRW/DVD or DVD±RW
- 5.2–6.0 pounds
- 10/100/1000 Mbps ethernet
- 802.11a/b/g (54Mbps) WiFi
- **Starts at \$1650**

Powerful

EmperorLinux specializes in the installation of Linux on a wide range of the finest laptops made by IBM, Lenovo, Dell, Sony, and Panasonic. We customize your choice of Linux distribution to your laptop and provide support for: ethernet, wireless, X-server, ACPI power management, USB, EVDO, PCMCIA, FireWire, CD/DVD/CDRW, sound, and more.

Rhino D830/M6300

Dell Latitude D830/Precision M6300

- Up to 17" WUXGA w/ X@1920x1200
- NVidia Quadro FX 3500M graphics
- 1.8–2.4 GHz Core 2 Duo/Extreme
- 512 MB–4 GB RAM
- 60–160 GB hard drive
- DVD±RW or Blu-ray
- 6.3–8.6 pounds
- 802.11a/b/g (54Mbps) WiFi
- ExpressCard/EVDO
- **Starts at \$1365**

Unique

EmperorLinux offers Linux laptops with unique features. Ruggedized Panasonic laptops are designed for harsh environments: drops, vibrations, sand, rain, and other extremes. ThinkPad tablet PCs are like other laptops, with an LCD digitizer for pen-based input both as a mouse and with pressure sensitivity for writing and drawing on-screen.

Raven X61 Tablet

ThinkPad X61 Tablet by Lenovo

- 12.1" SXGA+ w/ X@1400x1050
- 1.6 GHz Core 2 Duo
- 1–4 GB RAM
- 80–120 GB hard drive
- 3.8 pounds
- Pen/stylus input to screen
- Dynamic screen rotation
- Handwriting recognition
- X61s laptops available
- **Starts at \$2200**

REUVEN M. LERNER

Incremental Form Submission

A creative solution for solving Web service performance bottlenecks, or “ix-nay on the ottleneck-bay”.

Computers are amazingly fast. Think about it—we measure raw processor speed by how many instructions it can execute each second, and that number has gotten so large, we round off to the nearest hundred million.

Of course, it's often hard to feel that computers are all that speedy, especially when you're sitting around waiting for them to complete a task. Sometimes that wait has to do with complex algorithms that take a while to execute. But in many cases, the problem is a delay further down in the system, which is causing your end-user application to wait for a while.

This, I believe, is the major Achilles' heel of the world of Web services—Web-based APIs that are making it increasingly easy to combine (and manipulate) data from multiple sources. Web services may be revolutionizing distributed application development and deployment, but they make it tempting (and too easy, sometimes) to create software whose performance depends on someone else's system.

For example, let's assume you are offering a Web service and that your program depends, in turn, on a second Web service. Users of your system might encounter delays at two different points: your Web service (due to computational complexity, a lack of system resources or too many simultaneous requests),

or the second Web service on which yours depends.

Several commercial companies, such as Google, eBay and Amazon, offer Web services to the general public. But, these services lack any sort of uptime or response guarantee and often restrict the number of requests you can make. If you write a Web service that depends on one of these others, a rise in requests to your service might well mean that you temporarily go over your limit with these services.

This is particularly true if you allow users to enter one or more inputs at a time. For example, if you're running a Web-based store, you want to let people put multiple items in their shopping baskets. It's easy to imagine a scenario in which each item in the shopping basket requires a call to one or more Web services. If each call takes one second, and if you are allowed to access the Web service only every six seconds, a user trying to buy ten items might end up waiting one minute just to see the final checkout screen. If a brick-and-mortar store were to keep you waiting for one minute, you would be frustrated. If an on-line store were to do the same thing, you probably would just pick up and leave.

So, what should you do? Well, you could simply throw up your hands and blame the lower-level service. Or, you could contact the lower-level service and try to negotiate a faster, better deal for yourself. Another option is to try to predict what inputs your users will be handing to you and try to preprocess them, perhaps at night, when fewer users are on your system.

I've recently come across this problem myself on some of the sites I've been developing in my consulting work. And, I believe I've found a technique that solves this problem without too much trouble and that demonstrates how Ajax programming techniques not only can add pizzazz to a Web site, but make it more functional as well. This month, we take a look at the technique I've developed, which I call (for lack of a better term) incremental form submission.

The Problem

Before we continue, let's define the problem we are trying to solve. Users visiting our site are presented

Listing 1. pl-words.html

```
<html>
  <head>
    <title>Pig Latin translator</title>
  </head>
  <body>
    <p>Enter the words you wish to translate into Pig
    Latin:</p>
    <form method="POST" action="pl-words.cgi">
      <textarea name="words">Enter words here</textarea>
      <p><input type="submit" value="Translate" /></p>
    </form>
  </body>
</html>
```

Listing 2. pl-words.cgi

```
#!/usr/bin/env ruby
# *-ruby-*

require 'cgi'
require 'xmlrpc/client'

def pl_sentence(sentence)
  server = XMLRPC::Client.new2('http://127.0.0.1:9000', nil, 240)

  sentence_array = sentence.split

  # Send the words, and catch any faults that we find
  begin
    results = server.call("atf.pl_sentence", sentence_array)
  rescue XMLRPC::FaultException => e
    exit
    # puts "Error:"
    # puts e.faultCode
    # puts e.faultString
  end

  return results.join(' ')
end

# Create an instance of CGI
cgi = CGI.new("html4")

# Get the words to translate
words = cgi.params['words']
if words.empty?
  words = ''
else
  words = words[0].downcase
end

# Send some output to the end user
cgi.out {

  cgi.html {

    # Produce a header
    cgi.head { cgi.title { "Your Pig Latin translation" } } +

    # Produce a body
    cgi.body {
      cgi.h1 { "Pig Latin translation results" } +
      cgi.p { "Original sentence: '#{words}'" } +
      cgi.p { "Translated sentence: '#{pl_sentence(words)}'" }
    }
  }
}
```

with an HTML form. The form contains a textarea widget, into which users can enter one or more words. When a user clicks on the submit button, a server-side program takes the contents of the textarea and sends it to a Web service that turns each word into its Pig Latin equivalent. The server-side program retrieves the results from the Web service and displays the Pig Latin on the user's screen as HTML.

It goes without saying that this example is somewhat contrived; although it might be nice to have a Web service that handles translations into Pig Latin, it takes so little time to do that translation (really, a simple text transformation), that storing or caching this information would be foolish. That said, this example is meant to provide food for thought, rather than a production-ready piece of software.

Let's start with our HTML file, shown in Listing 1. It contains a short HTML form with a textarea widget (named words) and a submit button.

Clicking on that submit button submits the form's contents to a CGI program written in Ruby, named pl-word.cgi (Listing 2). There are two sections to Listing 2. In the first part of the program, we define a method, pl_sentence, that takes a sentence (that is, a string), turns it into an array of strings (with each word in one string), and then passes that array to our Web service (via XML-RPC). The second half of the program takes the input from our POST request, passes it to the pl_sentence routine, and then uses the output from pl_sentence to create a bit of nicely formatted (if Spartan) output for the user.

The key to making all this work is shown in Listing 3, which provides the code for our XML-RPC server. We begin by reading from a simple cache of English words and their Pig Latin equivalents. Again, it seems silly to store things in this way, when it's much faster simply to write the code that handles the Pig Latin rules. If you imagine that each translation takes several seconds, you can see how things could pile up quickly.

There are several things to notice in this program. One of the first is the use of an on-disk cache to store recently processed inputs. (Please don't try to emulate the simple and foolish way in which I implemented this; I ignored locking and permission issues.) The cache itself is a simple text file containing name-value pairs. Before computing the Pig Latin translation of each item, the Web service consults the cache. If the word is in the cache, the service grabs that value and almost immediately returns the translated value.

If the word isn't in the cache, it translates the English into Pig Latin, storing the values for the next time around. Again, this ensures that we have to work hard (that is, translate the word into Pig Latin) only if it fails to appear in the cache.

If you've never programmed in Ruby before, you might be put off a bit by this line:

*This is what Jeremiah does in his spare time.
Imagine what he does at work!*

SMART, CURIOUS, INQUISITIVE, MOTIVATED. Daring to take on the challenges that others won't. This is a White Oak employee on any given day.

```
words.map {|word| word.to_s}.each do |word|
```

This tells Ruby that it should take the array named `words` and turn each of its elements into a string. (If the element already is a string, it is unaffected.) We then iterate over each string (`word`) in the array, assigning the local variable `word` to each element in sequence.

With Listings 1, 2 and 3 in place, you should be able to translate sentences from English into Pig Latin without too much difficulty. You enter the English words into the HTML form, the server-side program calls the Web service, and the Web service takes care of things quickly.

Improving Performance

Now we come to the hard, or interesting, part of this project. If you can imagine that each Pig Latin translation takes ten seconds to execute, but less than one second to retrieve from the cache, you would want the cache to be used as much as possible. Moreover, given how long each word lookup takes, users will need a great deal of patience to deal with it.

The solution? Use Prototype, a popular JavaScript framework. Its `AjaxUpdater` will submit the contents of the textarea widget to a URL of your choice automatically—in this case, the same one that is used for POST—in the background, each time the text area is changed. Then, each word is translated while the user

Listing 3. `pl-server.rb`

```
#!/usr/bin/ruby

require 'rubygems'
require 'net/http'
require 'rexml/document'
require 'xmlrpc/server'

# -----
# Load the translation cache
# -----

dictionary = { }

puts "Loading cached translations"
translation_file = 'translations.txt'

if FileTest.exists?(translation_file)
  File.open(translation_file, "r").each do |line|
    (english, piglatin) = line.chomp.split('=')
    dictionary[english] = piglatin
    puts "'#{english}' => '#{piglatin}'"
  end
else
  File.open(translation_file, 'w') do |line|
    end
end

# -----
# XML-RPC
# -----

# Start an HTTP server on port 9000, to listen for clients
server = XMLRPC::Server.new(port=9000, host='127.0.0.1')

server.add_handler(name="atf.pl_sentence",
                  signature=['array', 'array']) do |words|

  words.map {|word| word.to_s}.each do |word|

    # Have we already seen this word? Don't bother to
    # translate it
    if dictionary.has_key?(word)
      puts "Grabbing translation of '#{word}' from the dictionary"
      output << dictionary[word]
      next
    end

    # If it's not in the cache, then go for it.
    piglatin = ''
    if word =~ /^[aeiou]/
      piglatin << word
      piglatin << 'way'
    else
      piglatin = word[1..-1]
      piglatin << word[0]
      piglatin << 'ay'
    end

    puts "Translated '#{word}' => '#{piglatin}'"

    # Cache it
    puts "Trying to cache..."
    dictionary[word] = piglatin
    File.open(translation_file, 'a') {|f| f.puts
      "#{word}=#{piglatin}"}
    output << piglatin
  end

  output
end

server.serve

output = [ ]
```

Web services may be revolutionizing distributed application development and deployment, but they make it tempting (and too easy, sometimes) to create software whose performance depends on someone else's system.

is filling out the text form, dramatically reducing the time needed to translate.

In other words, I'm betting it will take enough time for users to enter the entire sentence, that I can collect and translate most or all of the translated words while they're typing. Also, because I know that the Web service is caching results, I can pass the contents of the entire textarea every few seconds, knowing that retrieving items from the cache is extremely rapid.

The key to this functionality is the use of the `Form.Element.Observer` object in JavaScript. This object allows us to monitor any form element over time, submitting the form's contents to an arbitrary URL when the form element changes. We will use this, along with our knowledge that the Pig Latin server (`pl-server.rb`) caches words it has already translated, to submit the form every few seconds, even before the user clicks the submit button.

We do this by adding an `id` attribute, whose value is `words`, to our textarea, and also by adding the following JavaScript code:

```
new Form.Element.Observer($('words'), 3, translateFunction);
```

In other words, we will check the words in textarea for changes every three seconds. If something has changed, the browser invokes the method `translateFunction`. This function is defined as follows:

```
function translateFunction() {  
  
var myAjax = new Ajax.Request(  
  '/pl-words.cgi',  
  {  
    parameters: Form.serialize('form')  
  });  
}
```

In other words, `translateFunction` creates a new Ajax request in the background, submitting the contents of the form to the URL `/pl-words.cgi`—the same program to which the form will be submitted at the end of the process. But, for our incremental submissions, we care more about the side effects (that is, the cached translations) than the resulting HTML. So, we ignore the output from `pl-words.cgi`.

Because of how we built our server-side programs, they don't need to change at all in order for this Ajax-style addition to take effect. All we need to do is modify the HTML file, adding a few lines of JavaScript.

Now, of course, this doesn't change the amount of time it takes to translate each word or even an entire sentence. But, that's not the

```

point. Rather, what we're doing is taking advantage of the fact that many people tend to type slowly and that they'll take their time entering words into a textarea widget.

If users type quickly, or enter a very short sentence, we haven't really lost anything at all. It'll take a long time to translate those people's sentences, and they'll just have to wait it out. If people change their minds a great deal, it's possible we'll end up with all sorts of cached, translated words that are never going to be used again. But, given that the cache is shared across all users, it seems like a relatively small risk to take.

There are some things to consider if you're thinking of going this route—that is, combining an incremental form submission with a cache. First, notice we are iterating over each word in the textarea. This means there's the potential for someone to launch a denial-of-service attack against your server, simply by entering ridiculously long text strings into your textarea widget. One way to prevent this is to limit the number of words you check from any given textarea widget. You can, of course,

limit the number of words you're willing to translate from the incremental submission, rather than from the complete and final submission.

Another item to remember is that you should not expose your inner APIs. APIs are for external use; the moment people know your internal data structures and methods, they might use them against you. These examples didn't include any cleaning or testing of the data that was passed to the server; in a real-world case, you probably would want to do that before simply passing it along to another program.

Finally, if your site becomes popular, you might need more than one server to handle Web services. That's fine, and it's even a good idea. But, how many servers should you get, and how should they store their data? One possibility, and something that I expect to write about in the coming months, is Amazon's EC2 (Electric Computing Cloud) technology, which allows you to launch an almost limitless number of Web servers quickly and for a reasonable price. Combining EC2 with this sort of caching Web service might work well, especially if you have a good method for sharing dynamic data among the servers.

Conclusion

Web services are a wonderful way for servers to share data. But, when a Web service becomes a bottleneck, and when we lack control over the size of the bottleneck, we must try to find creative solutions. This month, we looked at something that I call incremental posting, designed to spread the burden over time, as a user is typing. Even if this solution isn't quite right for you, perhaps you'll be inspired in some way to incorporate this, or other Ajax techniques, into your own sites. ■

Reuven M. Lerner, a longtime Web/database developer and consultant, is a PhD candidate in learning sciences at Northwestern University, studying on-line learning communities. He recently returned (with his wife and three children) to their home in Modi'in, Israel, after four years in the Chicago area.

Resources

Programs this month were written in Ruby, a popular general-purpose programming language. You can read more about Ruby, and download or browse through the documentation, at ruby-lang.org.

If you want to learn more about the Prototype library for JavaScript, go to www.prototypejs.org.

You can learn about Ajax programming techniques from many sites. One of my favorite books on the subject is *Ajax Design Patterns* by Michael Mahemoff, published by O'Reilly. I also have found it useful and interesting to keep up on the (seemingly limitless) amount of JavaScript and Ajax news at www.ajaxian.com.

MARCEL GAGNÉ

Your Voice, Forever Etched in Electrons

You want to record a simple voice message on your Linux system. It seems like an easy enough thing—until you need a certain audio format, complex edits, special effects and other audio tweaks. However, it's still pretty easy.

That must be the 30th time I've heard you repeat that phrase, François. What are you doing? Trying to record a new voice message for our Asterisk Linux-based answering machine? But you keep repeating yourself. Don't you like any of the recordings you've made so far? *Quoi?* None of them have worked? Ah, here is the problem...the microphone isn't on. Wait! I see a second, similar, problem. Your mixer gain is set all the way down. Now try it. Much better, *non?* Finish this later, François, I can see that our guests are already arriving and we must be ready. Look sharp.

Welcome, *mes amis*, to *Chez Marcel*, where the best in Linux and open-source software is paired with superb wine from around the globe. Makes yourselves comfortable, and I will send my faithful waiter to fetch tonight's wine selection. François, we have a few bottles left of that Niagara Region 1998 Reif Estates Vidal Ice wine. Please fetch them from the cellar.

On tonight's menu, *mes amis*, we will examine sound recording tools for your Linux system. Recording audio is actually pretty simple, though you must remember to turn up the microphone on your desktop's mixer applet (Figure 1). Some systems, notebook computers for instance, have multiple inputs. In addition to the internal, built-in microphone, you may also have a jack to plug in a headset, which has its own microphone. Make sure you select the appropriate source.

Getting a sound sample is easy enough and doesn't require fancy software. Command-line tools that are very likely already included in your system will do the job nicely. For instance, look for a command called `arecord`, which comes with a companion program called `aplay`. Simply put, `arecord` is a sound recorder for the ALSA (Advanced Linux Sound Architecture) subsystem. Here it is in its simplest form:

```
arecord -d 10 myrecording.wav
```

The result is a WAV format file

named `myrecording.wav` that is ten seconds in length. The WAV format is the default, so if I hadn't given my file an extension, the result still would have been a WAV file. Other file formats (`au`, `voc` or `raw`) can be specified on the command line with the `-f` option. Plenty of options let you change the sample rate, number of channels and so on. Run the command with a `-h`, or check the man page for a list of available options. Here's another example:

```
arecord -d 15 -f cd secondrecording.wav
```

The really interesting option here is `-f cd`, a shortcut for `-f S16_LE -c2 -r44100`, which effectively means 16-bit, little endian, 2-channel sound and a 44,100Hz sample rate. Then, if you want, you can play that clip using the `aplay` command.

There are, of course, some limitations with such a simple program. For instance, what if you want another audio format? Or, what if you want to do some kind of special effect using that clip? This is where another great little command-line program comes into play. It's called `sox`, the SOund eXchange universal sound sample translator.

Let's say you want to convert an MP3 file to OGG; `sox` makes it easy:

```
sox audiofile.mp3 audiofile.ogg
```

Simple, *non?* The `sox` program also has a set of effects you can apply to your sound clip. For instance, let's do a two-second fade in for a voice clip:

```
sox voicefile.ogg newfile.ogg fade 2
```

As you can see, it's not difficult. To get a handle on the various effects, type `sox --help-effects=all`.

There are, of course, graphical tools for recording sound. For instance, the KDE desktop's multimedia suite includes a program called `KRec` (Figure 2), a very capable sound recorder that takes advantage of KDE's aRts sound system. Because of this aRts integration, make sure your aRts daemon is set to use full-duplex mode—you can enable this in the KDE Control Panel, `kcontrol`, under the Multimedia section.

To record a sound with `KRec`, start by clicking the New

Figure 1. Remember to set your microphone gain before you record.

icon on the top left (or click File on the menu bar and select New). Then, click the red Record button and begin speaking into your microphone. Recording and playback levels are displayed, as is positional information on the raw data being recorded. At the bottom, there are a series of dials that let you adjust the aRTS compressor settings. When you have finished recording, press the Stop button, rewind, then press Play to listen to your clip. When you are ready to save it, you can choose to keep the raw data or export it to a more familiar format, such as WAV, OGG or MP3. Click File on the menu bar and select Export.

For GNOME desktop users, we have the GNOME sound recorder (Figure 3), which is available from the Multimedia menu. Using that program, you can select your input source (internal or external microphone and so forth), and the audio file format from the Record as drop-down box. To start recording, click the red Record button and start talking, singing or reciting Shakespearean poetry—whatever turns you on. When you are done, click the Stop button (the gray square at the end of the icon bar). Then, click the Save button.

These are all easy ways to record sound, but editing is

Figure 3. The GNOME desktop provides an easy-to-use tool for simple recordings.

limited. You have only so much control over recording quality, and anything other than the simplest of edits can be difficult or impossible. That's where a program like Audacity comes into play.

Audacity is a wonderful, easy-to-use, audio editing program. With Audacity, you can record audio from a variety of sources, including a microphone—podcasts, anyone? You also can use it to convert audio files into other audio formats. Take your old records or tapes, clean up the noise, and convert them to digital audio so you can burn them to CD. Edit, cut, copy, mix, add special effects and splice sound sources to create new sounds. Audacity is a multitrack real-time audio editing system that can handle 16-, 24- and 32-bit samples. Audacity is also just plain fun. You can get a copy of Audacity from your favorite Linux distribution's repositories (or install disks), or you can visit audacity.sourceforge.net for the latest source. In the following examples, I am using version 1.3.3 beta.

Audacity starts with a blank slate by default (Figure 4). Along the top of Audacity's main window, you will find a pretty standard menu bar with access to various categories of tools in Audacity's toolbox. Directly below the menu bar and toward the center, a number of buttons reflect Audacity's audio editing nature. These buttons are Pause, Play, Stop, Skip to Start, Skip to End and Record. I mention these first because they are so familiar.

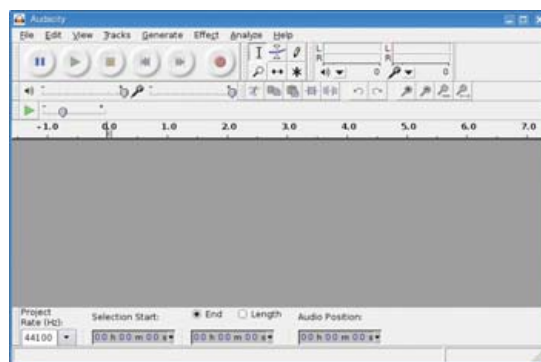

Figure 4. Audacity presents a blank slate for your creative urges.

To the right of those buttons is a compact toolbox with six small icons representing some common tools used in Audacity. The vertical bar icon, which looks like a capital I, is the Selection tool, and it is selected by default. Now, let's record something.

Make sure your microphone is plugged in, and then click the Record button to start. Be creative. Sing a short tune, recite a line or two of poetry, or just speak whatever nonsense pops into your head.

As you record, keep your eye on the microphone icon near the top on the far right. If you pause your mouse cursor over it, the tooltip reads, "Input level monitor - click to monitor input". When using a stereo input source, you'll see both the left and right channel levels being displayed, as shown in Figure 5. Of course, if you are using a single-channel

Change your pitch (without changing tempo), change the tempo, equalize soft and loud portions of your audio, add tremolo, remove noise and more.

microphone, you'll see only the right channel.

Figure 5. While you are recording, keep your eye on the input level meter on the top right.

As you record, you will see the appearance of an audio track with details about the quality of the recording—whether it's a mono or stereo recording and so on. When you are finished recording, click the Stop button. The full audio track remains with timing marks above (Figure 6).

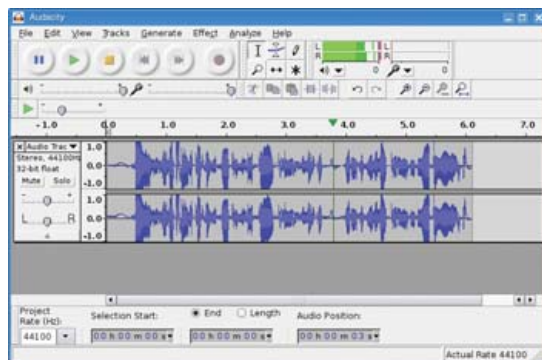

Figure 6. With a voice sample recorded, Audacity now displays one audio track.

As you can see from the preceding sample, I recorded a little more than six seconds of speech. To listen to the recorded track, click the Play button (Figure 7).

Figure 7. When playing back the sound clip, look at the meter directly to the right of the Record button.

At the bottom of the screen, there are additional details on the recorded track, the project audio rate (more on that shortly), as well as positional information.

Now that you have a sound clip to work with, this is a good time to save your work, and a good time for François to refill everyone's glass. While he does so, let me tell you about exactly what you are saving. At this stage, you do not have a finished product, but a work in progress. Audacity calls these projects. To save your project, click File on the menu bar and select Save Project As. A file navigation dialog appears where you can select the

folder that will house your project. Give your project a name (I'll call mine justplaying), and then click Save.

When you save a project, everything having to do with your project is saved, as it is at that moment. The only thing to remember is that Audacity project files (with an .aup extension) cannot be opened by other packages. The AUP file is accompanied by another folder of the same name, but with a _data extension. Now that your project is safe and sound, let's do some edits on that file.

Basic audio editing consists of identifying a section of track, selecting that section and performing some action on that section. Notice the first second or so of my recorded sample in the closeup in Figure 8. Yes, it's the dreaded dead air, the mini-uhm we tend to sneak in at the beginning of these things. I got lucky with that small pause, but it can often be a lot worse. Click the beginning of the sample at the zero mark, and drag the mouse pointer to select that pause.

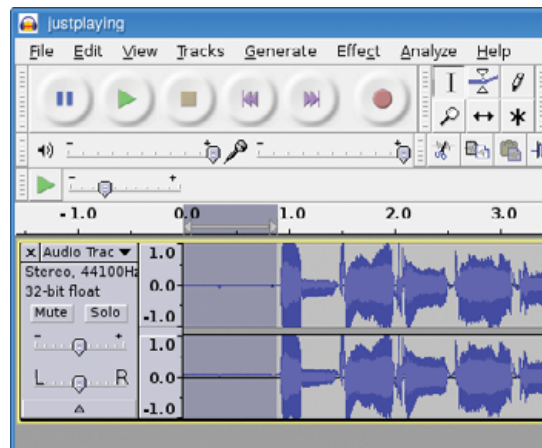

Figure 8. The first second of dead air in my recording is selected in preparation for trimming.

After you've selected the section of audio that contains the dead air, click the Play button to make sure that you haven't selected a portion of your speech. If necessary, adjust the selected area by positioning your mouse cursor over the beginning or end of the selected area and dragging to the left or right. The cursor changes to a hand with a pointing finger. If you are satisfied with your selection, click Edit on the menu bar and select Cut (you also can press the Delete key). Now, click the Play button again to listen to your file without that little bit of dead air. If you make a mistake, you can undo the changes by pressing Ctrl-Z.

With Audacity, you can let your creativity run wild with tons of included effects. Let's say, for example, you want to fade out the last few seconds of your recording. Select that section of the audio track, play it first to confirm you have what you want, and then click Effect and select Fade Out.

Perhaps you need to emphasize a few words. Again, select the section of audio you want, click Effect, and select Amplify. In the dialog that appears (Figure 9), amplify your selection by using the slider for a decibel increase. For finer

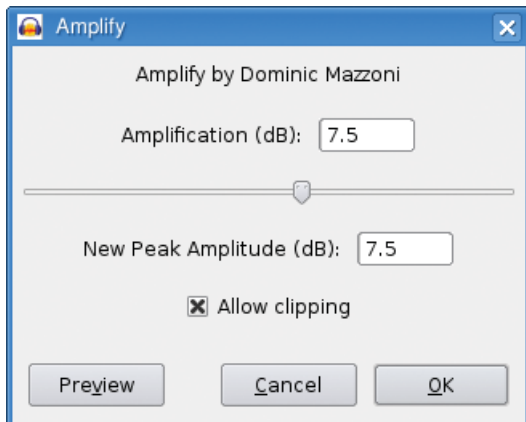

Figure 9. Despite the name, Amplify, this dialog can be used to decrease the volume as well.

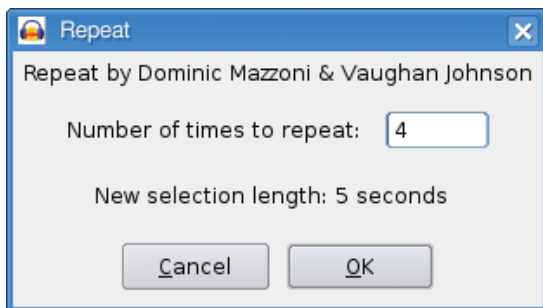

Figure 10. The repeat effect identifies the length of the segment and then asks how many times you want that segment repeated.

control, simply type the number into the Amplification (dB) field. I should point out that despite the name, Amplify, you can enter a negative amplification to reduce the volume. Click the Preview button to sample the effect before you click OK.

Sometimes, repetition is the best way to get your point across. Make your selection, click Effects on the menu bar, and select Repeat. The default is to repeat the selected audio ten times, but you can override that in the dialog (Figure 10). This repeat effect can be a lot of fun if you select a very short segment (or a single word) and set it to repeat for several beats.

I highly recommend that you spend some time playing with the effects—there are plenty of them. Aside from being a great way to waste time, you'll be impressed with the arsenal of effects at your disposal. Change your pitch (without changing tempo), change the tempo, equalize soft and loud portions of your audio, add tremolo, remove noise and more. The latest version of Audacity also has tons of additional plugins (under the Effect menu) to keep you entertained.

Okay, I want to cover one last effect, which I'll call "Nostalgia Time at *Chez Marcel*". One of my favorite effects is something those of us who can still remember vinyl albums will appreciate. On the occasional album, there were sections of a recording where you could play the sound backward to reveal a secret message. Granted, some of these so-called hidden messages were imagined, and

playing your album backward did nothing but add wear and tear to your needle, but others really were there. Well, you can create your own hidden message by using the Reverse effect.

So, where do you go from here? You've created some cool sound samples, played with them, cut and trimmed them,

amplified here, reverbed there, changed pitch and tempo, and otherwise created something totally new from what started out as a simple voice clip. What else is there? One option is to create your own podcasts, and I mention this mostly to bring up this point. When you are finished with your masterpiece, you want to save that file in a format that your listeners can use—that might be MP3, OGG, WAV or something else. Remember, up to this point, you are dealing with Audacity project files only. Click File on the menu bar and select Export. The Export File dialog appears (Figure 11) from which you can select a filename, location and type.

Mon Dieu! That clock on the wall cannot be right! Can it already be closing time? Ah, *mes amis*, I fear it may indeed be correct. Perhaps we can convince François to refill everyone's glass one final time before we must all head out into the open night. Raise your glasses, *mes amis*, and let us all drink to one another's health. *A votre santé! Bon appétit!* ■

DAVE TAYLOR

Yahtzee as a Shell Script? When Will It End?

Many a tear has to fall, but it's all in the game.

We seem to spend a lot of time talking about games and how to program them as shell scripts, don't we? From *Blackjack* to *Baccarat*, we're in danger of having to rename this column "game programming in the shell". But, that'd be crazy; who in the heck would write multiple games as shell scripts?

So, this month, I thought it would be fun to look at a dice game and see how the basic set of playing card functions we've written previously compare to the necessary functions to play a dice game.

Yahtzee was first introduced by Hasbro in 1956 as *Yacht* (having been invented by a wealthy couple on their fancy boat) and has been one of its best-selling titles since, spawning many variants, including hand-held electronic games and more. At its heart though, it's basically five-card draw poker played with dice. The wrinkle is that there are a set number of possible hands you can roll, and you attempt to achieve them all to maximize your score.

For example, roll a 3 4 4 4 5, and you might well pick up the 3 and the 5, hoping for either "your fours" (which you can get only once and want to choose when you have the maximum number of fours showing), or if you get five of a kind, a "Yahtzee", which is a big-points bonus but obviously difficult to achieve.

Like five-card draw, you can pick up zero to five dice and reroll them, but unlike five-card draw, you can do this twice on your turn, not once. So, perhaps the 3 4 4 4 5 rerolls as a 1 4 4 4 4. The second roll would then be to reroll the one and hope for another four. Either way, it's a good roll (unless you've already marked your fours).

Modeling It All

Dice are quite easy to create in a script—so easy it reveals how straightforward a script like liar's dice would be to write:

```
function rollDie()
{
    dieroll=$(( ( $RANDOM % 6 ) + 1 ))
}
```

If it's this easy to roll a die, though (dice, by the way, is plural of die), it'd be darn easy to write a quick *Dungeons and Dragons* dice roller too, as shown:

```
function rollDie()
{
    sides=${1:-6}

    echo "testing with a $sides-sided die..."

    dieroll=$(( ( $RANDOM % $sides ) + 1 ))
}
```

All you need to do is call `rollDie` with the number of sides you want on the dice it needs to roll. Using a 20-sided die? Try `rollDie 20` to see what rolls.

This also can quickly and easily be converted into a command-line function, so you could be a real *D&D* nerd by having a laptop adjacent and typing in `roll 20` every time you're actually supposed to roll the die.

But back to *Yahtzee*, yes? The easy part of modeling the game is the dice rolls. We need to have five dice, and that easily can be done with an array:

```
rollDie ; dice[0]=$dieroll
rollDie ; dice[1]=$dieroll
rollDie ; dice[2]=$dieroll
rollDie ; dice[3]=$dieroll
rollDie ; dice[4]=$dieroll
```

There, that's your first roll of the five dice. Displaying the results also is easy:

```
echo "You rolled " ${dice[0]} ${dice[1]} ${dice[2]} ${dice[3]} ${dice[4]}
```

Note carefully where I do and don't need to use the curly braces to get the array to work properly in the shell. Try this to see how it differs:

```
echo "You rolled " $dice[0] $dice[1]
```

Quite different results, as you can see. (And, as usual with shell programming, there's no useful warnings or error messages to clue you in to what might be wrong.)

Rerolling Specific Dice

Rolling the dice to get an initial hand is pretty straightforward, so let's take the next step and write the code to let you reroll any or all of the five dice twice to get your final hand.

There are a number of ways to ask for this sort of input, but to make it a bit chatty, let's simply present each

Listing 1. yahtzee.sh

```
#!/bin/sh

function rollDie()
{
    sides=${1:-6}

    dieroll=$(( ( $RANDOM % $sides ) + 1 ))
}

rollDie ; dice[1]=$dieroll
rollDie ; dice[2]=$dieroll
rollDie ; dice[3]=$dieroll
rollDie ; dice[4]=$dieroll
rollDie ; dice[5]=$dieroll

echo -n "You rolled [${dice[1]}], [${dice[2]}], [${dice[3]}], "
echo    "[${dice[4]}] and [${dice[5]}]"

echo -n "Reroll which dice? "

read answer
for reroll in $answer
do
    if [ $reroll -lt 1 -o $reroll -gt 5 ] ; then
        echo "Invalid entry: $reroll. Please enter 1-5"
    else
        rollDie
        dice[$reroll]=$dieroll
    fi
done

echo -n "Your new roll: [${dice[1]}], [${dice[2]}], [${dice[3]}], "
echo    "[${dice[4]}] and [${dice[5]}]"

exit 0
```

die in ordinal value and let the player enter the appropriate number to indicate that it should be rerolled. Um, let me show you what I mean:

```
echo -n "Reroll which dice? "

read answer
for reroll in $answer
do
    echo "Requested: $reroll"
done
```

Here, you might specify that you want die 1 and 3 rerolled by typing in 1 3. Tweaking this just a bit, the for loop then can test for the validity of each entry:

```
for reroll in $answer
```

```
do
    if [ $reroll -lt 1 -o $reroll -gt 5 ] ; then
        echo "Invalid entry: $reroll. Please enter 1-5"
    else
        echo "Requested: $reroll"
    fi
done
```

Now, of course, it's time for some actual logic here, not merely a rudimentary test. I've simplified things just a wee bit by using array indices 1–5 rather than 0–4, sacrificing the slot of entry 0 so that it's easier to work with the values. This means if you ask to reroll die 4, for example, it's just a reassignment of dice[4].

Here's the new, improved for loop:

```
for reroll in $answer
do
    if [ $reroll -lt 1 -o $reroll -gt 5 ] ; then
        echo "Invalid entry: $reroll. Please enter 1-5"
    else
        rollDie
        dice[$reroll]=$dieroll
    fi
done
```

You can see that it's quite simple, and if we're not afraid of the code stretching out a bit, we simply can copy and paste some of it to show our before and after rolls:

```
echo -n "Your new roll: [${dice[1]}], "
echo -n "[${dice[2]}], [${dice[3]}], "
echo    "[${dice[4]}] and [${dice[5]}]"
```

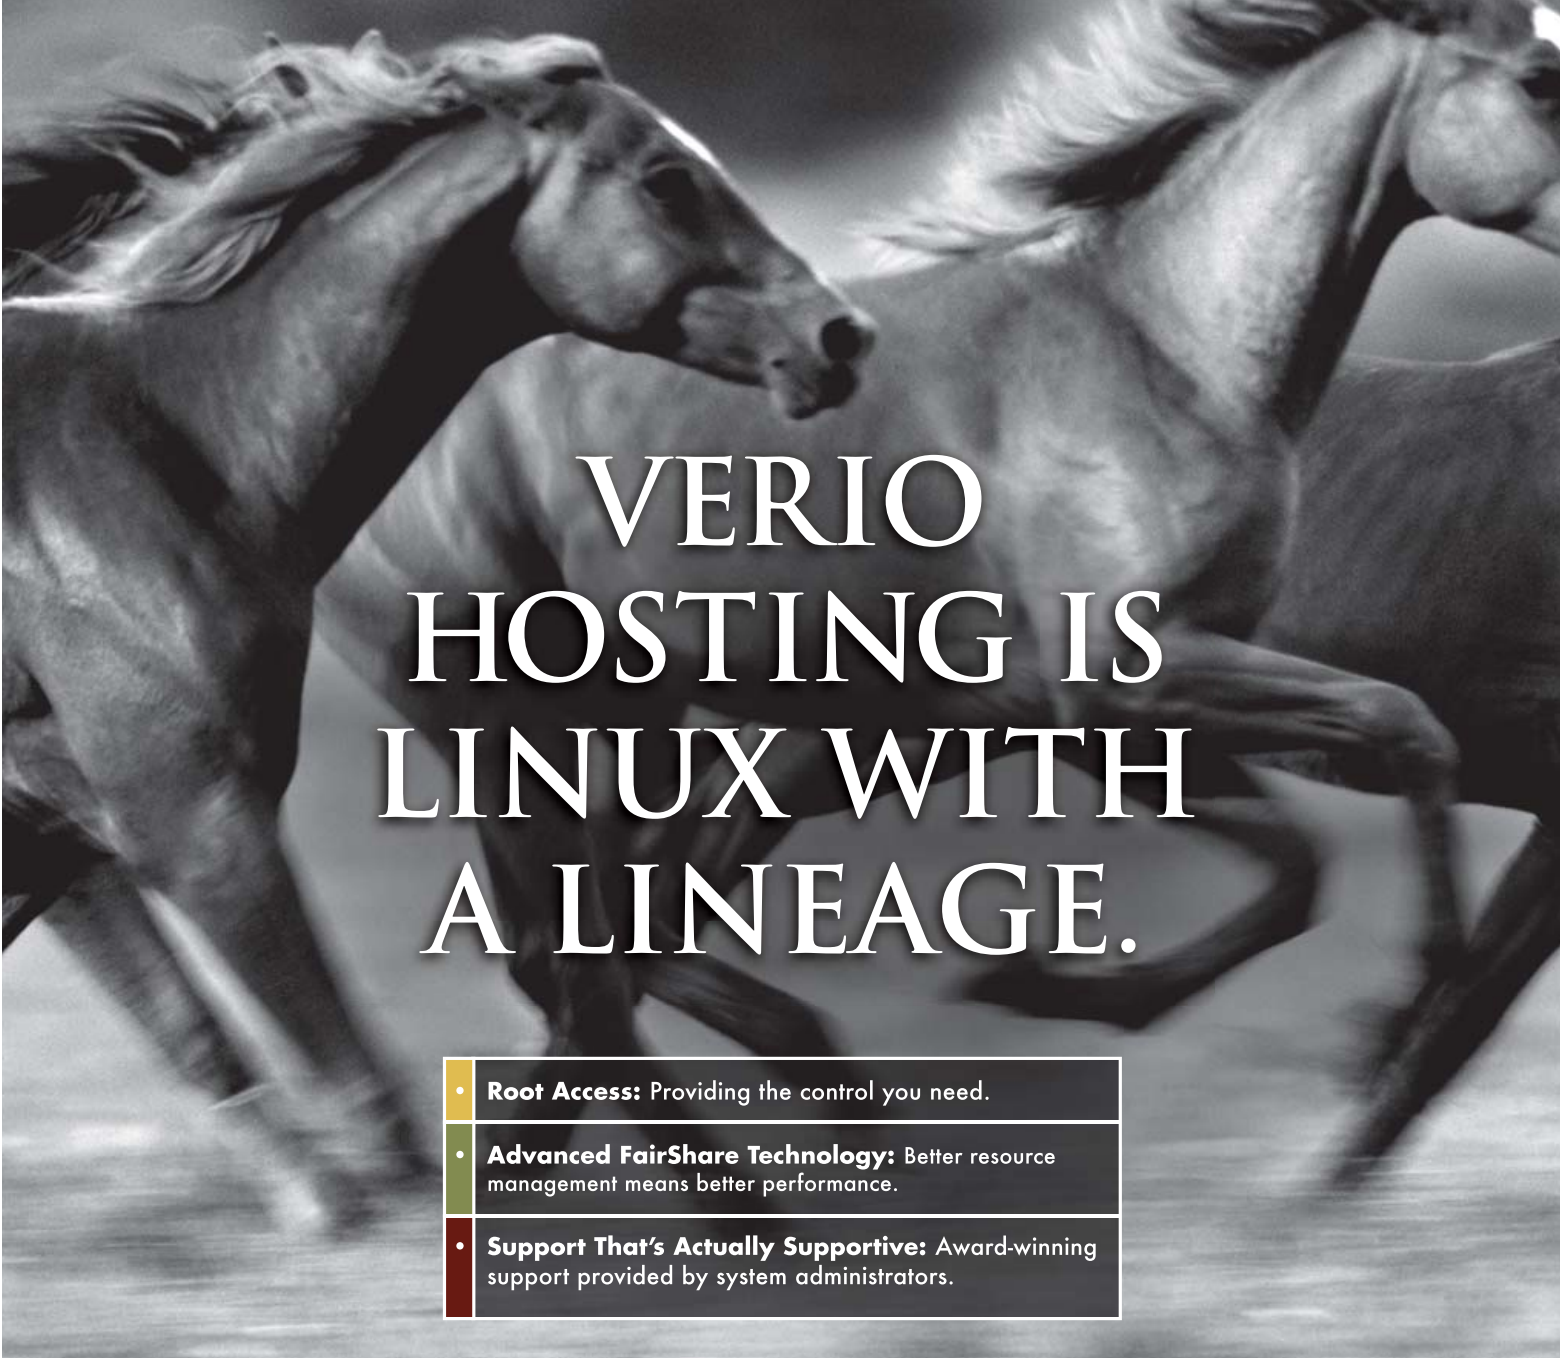

Let's run it once to see what's happening, and then next month, we'll start working on the actual game itself, rather than just the dice rolls:

```
$ ./yahtzee.sh
You rolled [2], [6], [5], [2] and [1]
Reroll which dice? 2 3 5
Your new roll: [2], [2], [4], [2] and [5]
```

Yes, I snuck in the notation of having the dice values shown within square brackets just for visual appearance. It makes the echo statements a bit more confusing, as you can see just a bit earlier, but the output is more attractive. ■

JON "MADDOG" HALL

Get FOSSED

David Trask leverages the flexibility and power of FOSS to create a waste-not-want-not approach to educational computing.

This month, I step outside my normal persona to describe a small conference named FOSSED (www.fossed.net). I attended two sessions of FOSSED, one in June 2007 and one in July 2007, which finished just two days before I wrote this article.

David Trask, a friend of mine, initiated FOSSED five years ago. David is an elementary schoolteacher in Maine, and he is "student focused". He often reminds people that his customers are the students, and in David's case, these are second- and third-grade students, eight to ten years old. David, like many teachers, always is asked to "do more with less", and in the course of trying to do this, he discovered free and open-source software.

David started using FOSS in his own school. He became a fan of the Linux Terminal Server Project (LTSP, www.ltsp.org) and started re-deploying cast-off equipment to create more computing nodes for his students. David also is a student of human nature, and as he started to deploy more and more of these systems for his own students, and as they started doing more and more in his own classes, he offered some of these computers to other teachers. David also is adept in telling stories about his young charges and how easily they adapt to FOSS while older people complain how hard it is. After a while, David began sending out e-mail messages regarding his successes to a mailing list read by Maine educators involved with technology.

Eventually, David realized enough people were interested in this topic that he decided to have a few seminars and actually demonstrate the capabilities. After a few of these seminars, David started talking about the possibility of having a conference specifically about the use of FOSS in grade-school education. So, five years ago, David and another FOSS enthusiast held the first educational FOSS conference at Gould Academy (a residential high school in Maine) and called the conference NELS, for North East Linux Symposium. They later realized that Linux was a small (although important) part of FOSS educational software, so they renamed the conference FOSSED.

In June 2007, right after school let out, 70 elementary-, middle- and high-school teachers and technologists descended on Gould Academy. Out of the backs of cars and trucks came systems removed from school labs and homes, networking gear and personal laptops for taking notes. In addition, several sponsors supplied a dozen or more thin-client systems and a server, so people could use them during the event. [Note to sponsors of other events like this: the thin clients went on sale after the event at a "special price" to attendees.]

By this time, David had picked up several other helpers. Matt Oquist, the founder of Software Freedom Day (www.softwarefreedomday.org), who also is a consultant to various school systems in the use of free software, helps David in the planning and execution of logistics and teaches some classes. Bill Sconce, a consultant and scripting wizard, gives courses in scripting languages for more-advanced participants to show how to maintain many systems using a shell script, Python and other scripting languages. Bryant Patton, a longtime advocate of computers in education and the founder of the National Center for Open Source and Education in Vermont, also helps out. But, David Trask remains the driving force and cheerleader, and for the past two years, the University of New Hampshire (UNH) has held a second session of this conference with almost as many attendees as the sessions in Maine.

Five years after David started the conference, the amount of software that exists for educational use is very impressive. A couple seminars are centered around the use of Moodle to plan and present classroom material. One teacher volunteered to talk about Web 2.0 tools and show the other teachers how some of the Web's new features could be used to stimulate student creativity. At the same time, she discussed doing this in a safe way and getting around the advertising bombardment that sometimes accompanies gratis sites.

Although a core component of the conference is LTSP usage and administration, it also has branched out to discussions on LDAP for ease of administration, IP Cop (for setting up firewalls), creating software packages (think .deb and .rpm) and a variety of other system-administration topics. It was interesting to see how one moment the person sitting next to me was a student in a class on how to use VMware effectively, and the next moment that same person was teaching a course on some other aspect of free software—teachers teaching teachers.

Sometimes the thing most obvious to you may be the biggest revelation to another person. I had not used VMware since its early days when it was difficult to install and get working. At the conference, I "installed" VMware (actually it was a package already done for Ubuntu), entered the key, installed an Edubuntu server on it and booted a thin client running off the virtualized server on my notebook—all of this while I was still editing and sending e-mail through my notebook's wireless card. I am now quite a fan of VMware, and I am sorry I haven't spent more time with it over the years.

On the other hand, when the teachers mentioned that

there was so much software on SourceForge that they didn't have time to evaluate it all, I suggested that they ask students to find, test and select software the class might want to use and present their results and reasoning to the class—the 21st-century version of the 19th-century book report. A stunned silence fell over the room.

At the UNH sessions, a group of high-school students and their advisers came up from the Arlington, Virginia, school system (an 11-hour ride by car in two vans) to demonstrate a project called CanDo that they had been creating. Then, after getting feedback from the teachers about new features and GUI changes, the students went into a two-day (and sometimes night) hacking session to implement those changes. It warmed my heart to see that the group of students was a diverse mixture of young men and women, different races and nationalities, and they all seemed to get along fine. This was the second year that they participated in the conference, and it was good to see some of the same faces return.

Finally, the teachers listened to and gave feedback to several of the vendors who had open-source products used at the event, and to one vendor who was struggling with whether the company should go open source and

the consequences of doing that. Direct feedback from customers is usually a good thing to have.

Many things impressed me about this conference, but one of them was the goodwill and camaraderie that managed to come through all the time—people working with each other and having fun learning. The organizers try very hard to have a comfortable venue and a relaxed schedule, and although it's too late to participate in a FOSSED event this year, you can start thinking about participating in next year's event, or (better yet) start thinking about creating a similar event in your own region of the world.

You can see a lot of what was done last year at www.fossed.net and participate in the FOSSED blog at fossed.blogspot.com. ■

DOC SEARLS

Atlas: Hoisting a New World of Search

There is history here. We first covered Jabber in the September 2000 issue of *Linux Journal*, more than seven years ago. At the time, Jeremie Miller, who invented Jabber, told me at least five years would pass before Jabber's protocol—later dubbed XMPP and approved by the IETF in 2003—would establish itself as a de facto standard. He was right.

We've stayed in touch over the years, as Jeremie's interests have spread outward from messaging and presence to other subjects—especially search. I guess it was about two years ago that he began to question whether search needed to be a single-source thing (for example, Google or Yahoo). That was when he also started talking about his new search project, called Atlas. Whenever I'd ask him what he was working on, he'd reply, "Atlas".

I was all for it, because I've felt from the start that search engines are essentially kluges meant to overcome a directory deficiency in the Web itself. I've also thought that, although there was good to be found in the chaotic nature of everything to the right of the first single slash in every URL on the Web, there was something inherently wrong about relying on massive commercial advertising-powered search engines—with their bots and crawlers and proprietary weighting algorithms chugging through constantly updated indexes stored in hundreds of thousands of servers—just to find stuff. And, although I agree with David Weinberger that *Everything Is Miscellaneous* (the title of his excellent new book), I don't like relying on Google, Yahoo or MSN alone (usually just Google) to tell me what I mean when I search for something. Nothing matters more than meaning, and I don't like seeing it supplied by what Jeremie calls a "text box dictatorship". In a May 28, 2007 blog post, he asks:

Why in such an advanced civilization have we become Knowledge Peasants who are so easily placated by the black magic of our Goovernor? Am I the only one wondering why these commercial boxes own such an important social function: what everything means?

The answer, he says, is:

Open open open! Open source, open distributed grids, open algorithms, open rankings, open networks of people cooperating to provide resources. The future of search is in open cooperation (and competition) based on a Meaning Economy—create meaning,

exchange meaning, serve meaning.

My vision begins with an *open protocol*, allowing independent networks of search functions (crawling, indexing, ranking, serving, etc.) to peer and interop. All relationships between these networks are always fully transparent and openly published. Networks exchange knowledge between them, each adding new meaning to the information, each of them responsible for the reputations of their participants and peers. This is the very foundation of a Meaning Economy.

Tomorrow now has a meaning that we can all help build.

Jeremie hasn't been the only one on the open search case. Jimmy Wales, prime mover behind Wikipedia, attracted attention in December of last year when he said, "I want to create a completely transparent, open-source, freely licensed search engine"—as part of Wikia.org, a community development companion to Wikipedia. In a December 29, 2006 interview (www.wired.com/techbiz/it/news/2006/12/72376?currentPage=2), *Wired* asked him for specifics about that. Jimmy's reply was, "We don't know. That's something that's really very open-ended at this moment. It's really up to the community, and I suspect that there won't be a one-size-fits-all answer. It will depend on the topic and the type of search being conducted." Subsequent interviews were similarly speculative and open-ended.

Then, on May 1, 2007, came news that Jeremie was joining the Wikia Project. In a prepared statement (news.com.com/2100-1032_3-6180379.html), Jimmy Wales said, "Jeremie is a brilliant thinker and a natural fit to help revolutionize the world of search....I believe Internet search is currently broken, and the way to fix it is to build a community whose mission is to develop a search platform that is open and totally transparent."

Atlas was unveiled in a post to a list on July 5, 2007 (lists.wikia.com/pipermail/atlas-l/2007-July/000000.html). In that post, Jeremie said his "large vision" is "enabling search to become a part of the Internet's infrastructure. Building on Atlas as an open protocol, search can become a fully distributed and interoperable world-wide community. All of the participants can interact openly and in any role where they believe they can add value to the network."

As for architecture, he offered this:

There are three primary roles within Atlas:

- Factory—responsible to the content.
- Collector—responsible to the keyword.
- Broker—responsible to the Searcher.

Each of these actors must interact with the others to complete any search request. Any two roles could be performed by a single entity (whereas if all three are performed by one entity, the result would be a traditional, monolithic search engine).

A Factory is akin to a crawler in today's search engines. An Atlas Factory must fetch and process the content as intelligently as possible, performing analysis (such as Natural Language Processing) and normalizing it into distinct units. A Factory shares its highly refined and processed output with one or more Collectors based on who they believe is best utilizing it.

A Collector absorbs and indexes output from one or more Factories, with one primary goal: ranking. An Atlas Collector must provide the most intelligent ranking and relationship analysis possible. A Collector has to compete for the output of a Factory, as well as compete to provide the best ranking quality for Brokers.

A Broker must provide a Searcher with the best possible results. It does so by combining diverse ranking results from Collectors and also by retrieving content from the original Factories. This last step, a Broker interacting with a Factory, is critical to maintaining a balanced ecosystem. All Factories must be aware of and approve how their results are being used and by whom.

Reputation and reward is bi-directional between all parties (Factory-Collector, Collector-Broker and Broker-Factory). Each entity may choose to interact on principle (free, Commons), attribution

(results provided by), or commercially (as a paid service). The Atlas protocol is purely a facilitator and does not restrict how the relationships between any entities are formed. In considering these motives for the various entities, it's likely that the free-based networks will tend to become more specialized, commercial ones will compete on quality, and attribution-based networks will mature in both directions.

This simple yet powerful division of roles, responsibilities and relationships will result in a distributed economic foundation for an Internet Search Infrastructure. The wire protocol and further definition of the interactions between these entities is openly evolving; anyone interested is welcomed to join the discussions and see the initial proposals at lists.wikia.com/mailman/listinfo/atlas-I over the coming weeks.

As a kind of gauntlet, Jeremie threw down a summary challenge, "Nobody will beat Google, but EVERYBODY will."

Vigorous discussion ensued, as a rapidly growing community of developers began getting into what Jeremie calls "the dirty work of building it openly now". As that work began, I asked him if it would be cool to flow some of our conversation over here to *Linux Journal*. He said sure, so here it is.

DS: There is always this tug between monolith and polyolith. The irony of the Net as a Giant Zero (world of ends) is that it is entirely polyolithic—or wants to be. Centralizing a future polyolithic protocol into a monolithic service is one way it starts. But the end state is polyolithic.

JM: I agree, it's inevitable. It's the being of the Net itself that ultimately demands it, but Google is fighting to be a monolith for as long as possible...and that's fine, they'll embrace Atlas when they see it providing value.

DS: In your announcement [above] I see the seeds of a credit-where-due-based economic system—one in which we might obtain finders fees, or something like that, as value is given for service performed.

JM: The attribution-based model, yes. Absolutely the middle man needs to be

involved in the transaction. Atlas doesn't flow the money, but it does flow the information and provide a framework. The same with advertising. Really, contextual ads are very helpful. I rely on them as a tool when using Google search. And in fact, that model is the *best* form of fighting Web spam.

How the system works, and who is involved in the flow of information, is completely transparent, so the three actors—a Factory, a Collector and a Broker—are all involved in providing a search result. A Broker works on behalf of the Searcher. They have relationships with the appropriate Collectors, plural, and perform the queries— assembling all the relevant “Knuggets” they get back from the Collectors, valuing them based on whatever metrics they want, including talking to a “sponsored” Collector who serves only commercial results, any “local” Collectors for regional areas, and so on.

Competition is fierce when anyone can be a Broker for almost no cost other than relationships. So, a Collector has one job, provides relevant results, and has to compete with anyone else to do so. And, it can judge the relevancy via any algorithmic, human-reputation-based, or combination.

DS: Open source at the production end has always been a meritocracy. Seems to me the equivalent with Atlas to “show me the code” is “show me the results”. Or at least, “show me the relevancy”. No?

JM: The Factory is managing commodity access to the refined content, doing all the work of normalizing the Web. Search results are just merit: who has the best. And a Broker going to many sources, many Collectors (there can be lots of them) gains lots of merits in different forms. So foxmarks has a great database of deep links that are very important to people. That way Mitch can serve high-quality results but only for certain categories of queries. And Wikipedia can serve another category of queries with high relevancy—as can local yellow-page-style systems, as can social networks for people queries.

DS: I see implicit in this a respect for the snowballing nature of knowledge, both for individuals and for groups. To be human is to grow what one knows. Authority is the right we grant certain others to contribute to what we know—and to change us in the process. Knowing more makes me different. As has been said elsewhere, “we are all authors of each other”.

JM: Yes, the fundamental unit of Atlas is a “Knugget”, a Knowledge Nugget essentially, a search result. A Factory adds value based on what it knows about the content; a Collector adds value based on what it knows about keywords and ranking Knuggets; and a Broker adds value based on what Collectors it knows and what value they provide in aggregate.

DS: Wikipedia, in growing its own relevance, is an

interesting example. I've been looking at radio stations and Webcasters. Wikipedia on the whole is a great source of info, but it's far from complete. And, it needs a better way to stay complete than just relying on narrow subject obsessives to stay on top of the current narrative. Search results that feed into better Knuggets that turn into better Wikipedia entries should be a Good Thing, no?

JM: Yes.

DS: Is a Knugget “something somebody wants to know”? I like the word. How about if it's a combination of keywords that may change over time?

JM: A Knugget is one unit of context, as I define it. It may be a title and a link; it may be a sentence saying something about a noun; it might be a row from a table of things. It's human-defined and, therefore, very fuzzy by its very nature. It's “What would a human recognize and make some sense of, out of context of anything other than what's contained inside of it?” The Web is human, not machine, and Atlas reflects that.

DS: I like contextuality. The summit of Mt. Everest can be an elevation, a sum of climbers, a single fact (such as, it is marine limestone).

JM: Yes. The very nature of Atlas is to demand that a Factory produces the best Knuggets, that a Factory “understands” the content as best as it can. It is a model that rewards human understanding and value first. All derivative knowledge is built atop that foundation, and we can reduce all of these inflated DB/schema disasters, which all serve the machine first. Atlas works in the same way that the Internet served people first, and servers/data centers second—and the Web content serves people first and software second. Search-as-Internet-infrastructure must serve people first.

DS: Yes. I think there is a Static (traditional Google) vs. Live (human, now, evolving) distinction here. Allow me to quote myself at a bit of length: “And as for live feeds of Knuggets as they are produced, any content provider can get the most value by generating these feeds of Knuggets into Collectors they trust, search results can be instantly rewarded, a Searcher can find that breaking-news article immediately.”

One becomes an Atlas Broker just by being involved, I would gather.

JM: Just by searching, and knowing whom to ask for results.

DS: How do you want to seed this thing? Where does actual use start first?

JM: An Atlas Broker should be living here in my IM client, using all this great context, LOCALLY, to search my IM history as well as provide the best relevant search results from any content store I want it to.

DS: Who is the Broker?

SUPERSIZE YOUR STORAGE 1TB DRIVES & QUAD-CORES

ABERDEEN STIRLING 56T

1U 14 Inch Depth Mini Rack

- Up to two Dual-Core or Quad-Core Intel Xeon processors with up to 1333FSB and 8MB Cache
- Intel® 5000V "Blackford VS" Chipset with 64-Bit Support
- Up to 16GB 667/533MHz Fully Buffered ECC DDR2 SDRAM
- Up to 1TB SATA Hard Drive
- 520W AC Power Supply w/PFC
- 5-Year Warranty

- 5-Year Warranty

Starting at **\$6,699**

JM: The Broker is a human. The Broker is just a service that uses as much context as you, the Searcher, wants to give it, and it talks to many Collectors to merge/provide the best results.

DS: So, how are you seeding this thing?

JM: I'm already starting to set up Atlas Factories. We may announce a contest to build open-source Collectors that can do different/cool things with, say, the Internet Archive. Once Atlas starts to breathe on its own, and can publish that archive either openly or gated (attribution-based or paid), or if it can rank Web results better for a certain class of queries, it can use that data as a Collector and offer that again, openly or gated. But that's speculative and premature. It's all wide open at this stage.

DS: Outstanding. I know some investors have leaned on Technorati to blow away the archives because that's not what they search. Yet.

I guess I need to get a sense of what a search might look like, and how it would come up with stuff that's different from Google's static search and Technorati's live (chrono) search. Would I go to atlas.wikia.org to search? Or to...where? Or is that question too static or site-based?

JM: I don't have a "static" presence for Atlas yet. Kind of refusing even to do that for whatever reasons. Just a link to the mailing list for now is all there is. Someday there will be a presence, but the discussion is more important right now. I like it that all people can do at the moment is discuss.

DS: I'm just looking at how to help people conceive What It Is. Is it a site? A service that other sites, or even IM systems, or cell-phone apps, can use?

JM: Atlas is an idea, a model and, ultimately, a communication system between two people: the one that wants to learn and the one that wants to teach/share. It's just another communication platform, but the people talking don't know each other yet. Like all good Internet systems, it will live under the hood, behind text input boxes everywhere.

DS: In that respect, it's more like the Jabber "platform" than the AIM or Skype "platforms".

JM: Yep, in that Google, Yahoo and Ask are the IM silos, and Atlas is the distributed/open Jabber model.

DS: Good. I get that. Is Atlas code that sits somewhere and is given a bunch of stuff to look at? If so, where does it live? Is there a drawing we can use? Some kind of simple whiteboarding?

JM: Where stuff is almost doesn't matter. As far as visualizations go, the "logical" one is really Factory→Collector→Broker, but the technical one is more of a triangle, as the Broker talks to the Factory in the end to get the Knuggets...but basically no, there's nothing visual yet. A Factory is going to "look" like a pile of search results ordered based on the content source alone. A Collector will aggregate/order

them. And a Broker will aggregate from lots of Collectors the ordered results, merging them, getting the snippets from the Factories they came from, and presenting them. By the way, someone made the first visualization of the model (Figure 1).

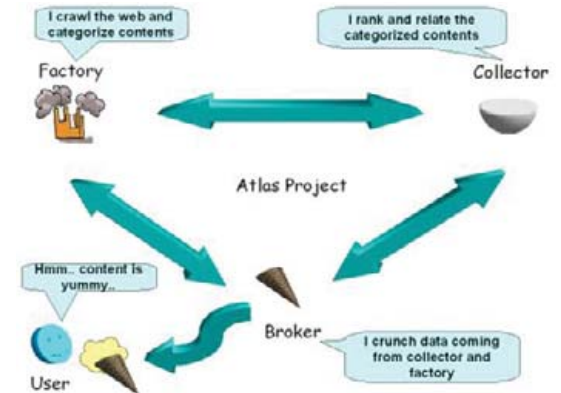

Figure 1. Visualization of the Atlas Model (from search.wikia.com/wiki/Atlas)

DS: Where would they live? The actors...Factory, Collector, Broker...or the code for it all?

JM: Oh, anyone can run any of them. There will be open-source projects to provide each of them. But, there should be thousands of each, running everywhere around the world. Just like Jabber, e-mail and Web servers. They just talk to each other with a protocol. There can be locale-based specific instances, ones for different languages, ones for types of content (images, videos), ones for topics (gaming, finance)—whatever people want to do/specialize in. People can run them for whatever reasons they want. A Broker is really the endpoint, so the nature of the search has the Broker engaging the relevant Collectors. A Broker is doing what the word really means, brokering your search to lots of sources for the best results. A Broker is what would likely be built in to your browser or whatever is driving an input box anywhere.

DS: I like the way it maps to the real world.

JM: It doesn't force an operational model, and it just goes with whatever motives people have to run it. The good part is that it will work only if people find it valuable enough to run it; those are the best kinds of systems. So is all of this clear as mud?

DS: Good mud!

JM: Thanks.

For more, look up Jeremie and Atlas on Google. Until you can do the reverse. ■

AML's MT7570 Vehicle Mount Terminal

If your forklift needs a Linux-driven data-capture device, AML hopes you'll use its new MT7570 vehicle mount terminal. The MT7570 is designed for "real-time receiving, put-away, picking and shipping applications in harsh industrial environments", and it integrates securely into existing wireless networks. Full USB and RS-232 serial connections, as well as optional Bluetooth WPAN communications, provide connectivity to peripheral devices, such as bar-code scanners and printers. Construction is rugged. The MT7570 has a bright display for dimly lit environments and can withstand dust and water deluges. The device is available with either embedded Linux or Windows XPe, and both systems include terminal emulators (VT100/220, TN5250, TN3270), Web browsers and a Skype client.

▶ Silicon Mechanics' Bladeform 8100 Series Blade Server Platform

Silicon Mechanics recently rolled out its new Bladeform 8100 Series of blade servers. The firm describes the line as "a family of modular computing products designed to address a wide range of high-density computing challenges by allowing multiple servers to be contained within one easy-to-manage system." Series components include the blade server enclosure, the 8110 server blade (dual Intel Xeon), modular networking and interconnect components. Some of the key features include a modular enclosure with support for up to ten server blades, up to four redundant load-balancing power modules, 90%+ efficient power supplies, up to 2GB Ethernet switches with ten external ports each, InfiniBand expansion adapters and switch support, and remote management capabilities.

www.siliconmechanics.com

HPC Systems' HiPerStor NAS Product Line

We've been informed of HPC Systems' HiPerStor, a new line of network-attached storage products. The line is targeted at three different product segments, namely SOHO/home, SMB and SMB with advanced needs. The line also features iSCSI technology, upgrade to InfiniBand, TOE NICs or 10GbE NIC, integrated volume replication and snapshot, support for disk encryption, secure Web-based management, a range of user-authentication options and more.

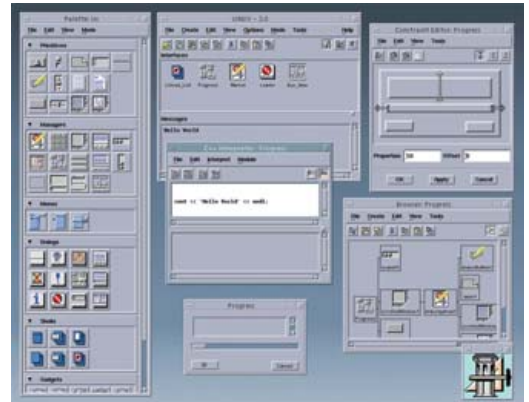

www.hpcsystems.com

Integrated Computer Solutions' UIM/X

We bid a warm Linux-community welcome to Integrated Computer Solutions, which recently released version 3.1.1 of UIM/X, a client/server application-development tool that now also runs on Linux. UIM/X enables developers to build Motif GUIs "in a fraction of the time it takes by hand", say the folks at Integrated. They also claim that UIM enhances programmer productivity by enabling the creation, modification, testing and code generation for the user interface portion of an application with a single tool. UIM/X supports the most current version of Motif (2.x) and runs on Solaris, HP-UX and Red Hat Linux.

www.ics.com

Storix, Inc.'s SBAdmin

In other news from LinuxWorld, Storix, Inc., released SBAdmin v6.2, touted as the first backup and system recovery solution to integrate with IBM's Tivoli Storage Manager (TSM). SBAdmin complements TSM by expanding on its features and capabilities for Linux and AIX systems. SBAdmin also writes directly to the TSM server, which cuts extraneous steps, saves time and increases reliability. In addition, the application provides TSM users with disaster-recovery capabilities, including a feature called Adaptable System Recovery, which enables system restore to the same or dissimilar hardware.

www.storix.com

64 Studio

Although I fear Dave Phillips will scoop me on his "Studio Dave" blog, let it be known that 64 Studio 2.0 Electric has been released. 64 Studio is "a GNU/Linux distribution tailor-made for digital content creation, including audio, video, graphics and publishing tools." A remix of Debian, 64 Studio comes in both 64- and 32-bit flavors, allowing it to run on nearly all PC hardware. The distro combines the stability and quality of Debian Etch with a specialized real-time preemption kernel and the latest creative tools demanded by multimedia artists. The developers aim to rocket you from blank hard drive to a fully hardware-optimized and usable creative desktop in just half an hour.

www.64studio.com

Black Duck's ProtexIP

At LinuxWorld San Francisco, Black Duck Software announced version 4.4 of the firm's protexIP/development, "a platform that helps companies govern how their software assets are created, managed and licensed." ProtexIP helps developers and legal counsel in managing the use of code from open-source projects that have both decided to switch to GPLv3 explicitly and those that have decided not to switch. It also includes an enhanced KnowledgeBase, a library of open-source and vendor-added code software components that includes detailed licensing information for more than 140,000 components.

www.blackducksoftware.com

The Tornado M20 Phone and Digital Media Center

Why settle for VoIP when you can pack
digital media in the same package?

MIKE DIEHL

When I considered evaluating SysMaster's Tornado M20 Media Center, I thought I was simply evaluating a video/voice IP telephone. Imagine my surprise when I discovered that it also could handle IPTV, streaming audio, stored graphics, IM, e-mail, RSS news and weather! I thought all it needed was a built-in calculator. Then, I read the Owner's Manual and discovered that it does have a calculator function. Wow! All this inside a box the size of an average speaker phone, and it even has space for 10Mb LAN, 802.1a Wi-Fi and a 3.5 color video screen. For about \$250 US, this device seems to be able to do everything my MythTv system can do, but it's *much* smaller!

Enough hype. Let's talk about practical issues.

As soon as I unboxed the unit, I was immediately struck by how heavy it was. This is not a phone you'll be dragging across your desk every time you lift the handset. When you put this unit on your desk, it's going to stay where you put it, and it's going to look nice sitting there. The M20 is a very clean, professional-looking phone.

Appearances are more important than you might think. I once was involved in a Voice-over-IP (VoIP) evaluation project where we set up a VoIP system and deployed a few phones for potential users. The prevailing comments we received from the users were that they liked the system. They liked the sound quality. They hated the phone. They said it looked too much like a toy. Obviously, we ended up taking another direction.

The M20 is black and silver-tone with clearly labeled buttons. There are no silly icons next to each button to make you guess what the button does. The handset, though perhaps a bit light, is comfortable to use. The color display and pivoting camera on the side of the unit tease functionality beyond mere voice communication.

The M20 is a four-line VoIP telephone that uses the SIP protocol to make and receive voice and video phone calls.

Video conferencing uses the H.264 protocol. For voice calls, the device can use the G.711, G.729 and G.726-32 codecs. For video calls, the unit supports H.263. Streaming media uses MP3 and MPEG-4. The unit's network configuration is done via DHCP, PPPoE or can be done manually. The rest of the configuration is done with a Web interface or a central provisioning mechanism via HTTP. As far as I can tell, there is no closed or proprietary functionality in this unit, which is important to me as a Linux and open-source advocate.

Because there are many voice-only VoIP phones out there, most of which are considerably less expensive, I opted not even to bother testing the voice-only capability and jumped straight to the main event, video. So, I asked one of the technical-support staff members at SysMaster to initiate a video call to me.

When the M20 receives a call, it indicates that it is a video call by displaying a V next to the caller-ID information on the display. If you want to establish a video call, you simply press the VIDEO button on the phone. On the other hand, if you want to establish a voice-only call, you pick up the handset, just like a regular phone, and the video function is disabled. Placing a voice or video call is done similarly.

Before we started our video call, the technician made sure I understood that the quality of the call was limited by the available bandwidth. I was using a residential DSL connection, so that would be the limiting factor. However, when we made the call, I didn't feel limited at all.

I was able to see the technician clearly, and in color—the color was a bit washed out though. Later, I discovered that the video camera was quite tunable, and that the camera's brightness, sensitivity and hue were all adjustable. I suspect his camera was just poorly adjusted. When I was playing with the phone earlier that morning, I was able to use the camera and see myself on the display, in full, vivid color. As scary as that was, it wasn't the phone's fault.

»» The SysMaster M20 VoIP phone is actually a digital media center.

As with any CCD camera with a slow frame rate, objects that are moving quickly tend to blur, but normal speaking and moving looked natural. However, when the technician waved his hand across the field of view to demonstrate the effect, the blurring was apparent. The default frame rate of 3–5 frames per second can be adjusted, but it seemed adequate for normal usage. Adjusting it much higher probably would have exhausted my available bandwidth and caused the call quality to drop sharply.

Even though we had a full video stream between us, the sound quality was still quite usable. The sound quality wasn't quite up to the level of the Polycom 501 I use at home, but in my opinion, nothing is. Even so, it was better than many VoIP phones I've used in the past.

The M20 supports all of the normal call functions, such as call forwarding, call transfer, hold, do-not-disturb, message waiting and voice mail. The phone supports Network Address Translation (NAT) as well as multiple server registrations.

In addition to normal call features, the M20 can function as an alarm clock by sounding the phone ringer at preselected dates and times. But, you can take it further than that. The device also can be configured to call an external phone number at a preselected time.

The device can store up to 80 voice-mail messages locally. The voice-mail system amounts to an internal answering machine, but at least it doesn't require a centralized server. Recorded messages are easy to retrieve via the menu or with a Web browser. The company's literature boasts advanced IVR (Interactive Voice Response) capability, and I think you'll agree I've got enough to write about as it is without getting into that function in any depth.

I'm told that the devices will auto-discover each other on the same network and establish a peer-to-peer telephone PBX configuration. So, it's a pretty well-rounded SIP phone.

After hanging up with the support technician, I decided to

watch some TV—IPTV, that is. Accessing the IPTV feature is easy using the on-screen menu. Once activated, the IPTV feature displays a list of available channels. A channel is selected by pressing the up and down buttons on the phone and then by pressing the OK button to begin viewing. The color display is simply stunning! I watched a soccer game on the unit; the field looked green, and the players didn't. Flesh tones were realistic. Motion was smooth without any hint of ghosting. Once in a while, I noticed some video artifacts, but that probably was due to bandwidth limitations or packet loss.

Using the built-in PVR function is much like programming a VCR. You select the date, time and channel, and at the designated time, the system either can switch to that channel and allow you to view the program or record the program for later viewing.

After changing channels to watch Shakira do her thing for a while, I decided to check out the M20's streaming audio feature. Streaming audio works about like you'd expect and sounds as good as most of the small radios people bring to work. But, that's where the three RCA plugs (both audio and video) on the side of the unit come into play. The M20 can be connected to standard AV equipment allowing you to take advantage of the bigger screen and better (amplified) speakers you probably already own. I easily could see using this unit, connected to The Big Amp in the living room, to play streaming music at parties or while we worked around the house. In my experience, Internet radio stations tend to play better music than over-the-air radio stations, so this would be a great thing to have at the home or office.

Any time I see a device with a USB port on it, it piques my interest, and the M20 was no exception. Once I plugged a pendrive in to the port, located on the back of the device, I was able to play any MP3, AVI or MPEG file on the drive as though it were a streaming media

FEATURE Tornado M20

source. I was a little dismayed to discover that plugging in a USB keyboard would crash the phone. USB keyboard support might have been nice for some of the messaging features discussed later.

The Owner's Manual indicates that the phone can scan the network for open shares that contain music and video files. I wasn't able to test that feature in time for this article, but you can bet I will soon, and the configuration options indicate that this should be fairly easy to do.

I really like reading news via RSS. Usually, you get a lot of diverse headlines and just enough summary information to let you determine whether the article is interesting enough to read in depth. However, this function on the M20 points out its two biggest weaknesses. First, the font is small and sometimes difficult to read. It is readable, but it takes some time to get used to it. But, the biggest problem comes from the fact that if you see a news headline you want to read more fully, you can't, because the M20 doesn't have a Web browser. Now, I understand that it's asking a lot to embed a Web browser in a telephone, but the newsreader feature just screams for it.

The M20 has a weather function that displays the local weather forecast for the next four days. Having gone through all of the configuration options, I'm not sure how this function works. I suspect that the weather information is pushed to the phone from a central server. Other minor services worth mentioning include a stock tracker, currency converter and, yes, as I noted earlier, a calculator. The M20 also has e-mail, instant messaging and SMS messaging features.

I wasn't able to test the e-mail capability directly, as the unit supports only the POP protocol, and my Courier POP server didn't want to

cooperate. However, explaining this feature is fairly easy. Once properly configured, the M20 can be used to check a user's e-mail quickly. The M20 doesn't support sending or replying to e-mail, only reading it. Now, at first, this may not seem like a very useful feature, but imagine rushing into your office on your way to an 8:00am meeting and using your telephone to skim your incoming e-mail quickly to check for any important messages. Now, imagine being able to do this in less time than it takes your PC even to boot up. How I wish the unit supported IMAP, but it would be worthwhile for me to configure a POP server just to use this feature.

Because the M20 lacks a keyboard, the IM function seems like it would be a bit cumbersome. But, as the unit supports ICQ, MSN, AOL and SMS messaging, it's very much worth mentioning. The initial configuration of the IM client is done via a Web browser. Once configured, you can send and receive instant messages on any of the supported networks. Sending a message involves using the phone keyboard to type messages, just like you would to send an SMS message on a cell phone.

So, as you can see, the M20 packs a lot of features in one little footprint. But, how well is it supported? As part of this evaluation, I had intended to contrive a fictional, yet plausible, problem with the unit and call SysMaster's tech-support line. Fortunately for me, the unit arrived misconfigured, and I had a perfect opportunity to visit with one of SysMaster's support technicians.

I already had determined that the SIP password had been misconfigured, but I let the technician guide me through resolving the problem, which he did in a logical progression—all the while exhorting various features of the device that he thought I may not have been aware of. He obviously knew the equipment and the technology. I was relieved not to be talking to someone who was simply reading a script.

As you might imagine with a device as sophisticated as this, configuration is everything. Sadly, very little of this configuration is exposed via the built-in video screen. Almost all of the configuration is done with a Web browser via HTTP. Because the Web-based administration console didn't work with Konqueror, I had to use my second choice, Mozilla Firefox, which worked well. At least I didn't have to resort to some other buggy browser. The administration console wasn't as straightforward as I would have wished. There is a lot of configurability in this device, but in my opinion, it isn't well organized.

So, despite a few quirks here and there, this is an amazing device. The M20 brings video, voice and text communications together in one convenient platform. Wireless, as well as LAN connectivity, plus its adherence to open standards, allows the M20 to be deployed just about anywhere. ■

"Building a Digital Lifestyle with Open-Source Technology" by Mike Diehl, *LJ*, October 2006 (about my MythTV and VoIP configuration at home): www.linuxjournal.com/article/9111

Growing a World of Linux Professionals

We at the Linux Professional Institute believe the best way to spread the adoption of Linux and Open Source software is to grow a world wide supply of talented, qualified and accredited IT professionals.

We realize the importance of providing a global standard of measurement. To assist in this effort, we are launching a Regional Enablement Initiative to ensure we understand, nurture and support the needs of the enterprise, governments, educational institutions and individual contributors around the globe.

We can only achieve this through a network of local "on the ground" partner organizations. Partners who know the sector and understand the needs of the IT work force. Through this active policy of Regional Enablement we are seeking local partners and assisting them in their efforts to promote Linux and Open Source professionalism.

We encourage you to contact our new regional partners listed above.

Together we are growing a world of Linux Professionals.

Stable. Innovative. Growing.

OpenMedia myPVR 2.0

A nicely polished Myth configuration on excellent hardware with slightly weak HD performance.

JES HALL

MythTV is arguably the most popular multimedia platform for Linux. It has excellent support for television—allowing you to pause, fast-forward and rewind live TV streams by spooling the stream temporarily on disk. It has commercial detection, so you can skip advertising, and it can use a variety of tuners and video input devices, including DVB- and ATSC-based digital tuners, as well as traditional analog tuners both with and without hardware MPEG-2 encoders.

It also includes a music player interface capable of ripping, encoding, sorting and playing most popular audio formats, with nifty full-screen visualisations. It will rip and transcode DVDs and play almost any video format you can imagine off the hard disk.

One of the weaknesses of MythTV is that it's not very easy to set up and configure; it's hours of hard work for people who know what they're doing—vastly beyond the capabilities of average consumers.

myPVR, from OpenMedia (openmedia.co.nz/openmedia/content/section/3/44) provides a PVR solution built on MythTV that smooths over most of the rough edges. OpenMedia has put a lot of energy into polishing the MythTV interface, and it shows. When requesting a unit to test, we were asked what kind of display we'd be using, so that the profiles could be set up for us. When it arrived, it worked straight out of the box, without any configuration required, and all of the PVR's functionality could be accessed using the remote control. The New Zealand TV channel listings already were set up for us when we turned on the device.

Figure 1. myPVR Default Theme

- » Time from box arriving to media playing: **two minutes.**
- » Time from box arriving to first crash: **ten minutes.**

In order to stress-test the system, we played BBC's *Planet Earth* in 1080p H.264. It tried gamely, but we managed to crash the media player in fairly short form. This is excusable though, as almost nothing manages to play H.264 content well on Linux. It did, however, perform very well on 720p HD content and SD content. The sound card was very well isolated, with crisp sound that had almost no discernable hiss, even when we turned up the amp as high as it would go. The box itself is a little noisy—if you were to have it sitting across the room, it probably wouldn't be noticeable, but behind the couch in our Official Audio/Visual Testing Suite (er, Jes' living room), the fan noise was audible during very quiet scenes. Still, we were very pleased with the choice of hardware.

Some other nice touches are a slick default theme, although it is a little like Windows Media Center. The New Zealand channel guides were programmed for us already, as well as little touches like the official channel icons. The unit itself looks very appealing, with a slick black case and muted-blue glowing LCD showing the internal temperature and fan speed.

Some fun games were pre-installed, including *Frozen Bubble*, *Tux Racer* and the XMAME emulator. The specifications claim support for USB gamepad and joystick devices, but unfortunately, we couldn't get it to work. We feel this is probably a make-or-break issue for gaming on the device—if USB gamepads worked without requiring arcane configuration, we imagine it would be quite

popular for casual gamers who were not interested in buying a dedicated console.

Another excellent improvement from the default MythTV distribution is the ability to download and apply updates to the software from OpenMedia, using a reasonably simple update interface and a tool to configure networking easily.

Figure 2. myPVR TV Interface

Steven Ellis from OpenMedia was kind enough to talk to us about MythTV, his product and DRM.

JH: So, how did you get started in MythTV?

SE: I played with video codecs back in the UK as a developer, so I've always been into that side of things. I kept an eye on Freevo and MythTV and did test installs, but I never felt the hardware was good enough for what I was after. Plus, one of the guys at my old job was playing around with TiVo and MythTV, which gave me some exposure. Then, about 18 months ago, I felt there was a good-enough hardware platform for my needs, which eventually became myPVR 1.0.

JH: What were the issues with the previous hardware platforms?

SE: Speed wasn't there to do HD, or you had to do a lot of cooling. I was after as integrated a solution as possible, and it had to be future-proof with good composite/video TV out as well as DVI/HDMI support. The NVIDIA 6150-based platform was perfect—great graphics with good drivers, excellent TV out and all integrated into the MB.

JH: How do you feel about MythTV as a platform—how far it's come, and where it's likely to go?

SE: The video side of it rocks, but for music, it has a long, long way to go.

OpenMedia myPVR 2.0 \$1,999 NZD (\$1,565 US)

HARDWARE:

- » ASUS/nForce Socket AM2 Athlon 64 motherboard.
- » AMD Athlon 64 3600 X2 CPU.
- » Dual-layer DVD+RW with DVD-RAM.
- » 512MB DDR2 SD-RAM.
- » Gigabit Ethernet.
- » High-definition audio with analog and digital outputs.
- » NVIDIA 6150 integrated HDTV-capable video.
- » 250GB SATA hard disk.
- » FireWire, front and rear.
- » Six USB 2.0 ports.
- » Hauppauge MPEG-2 video capture card.
- » Remote control.

We tested with a Panasonic PT-AE900u 720p projector and a standard 29" PAL television set.

People who have used other PVR software solutions are always blown away by how quick MythTV is, but they are shocked at the MythMusic plugin. It was okay three years ago, but it doesn't measure up against iTunes. As a platform, it provides an amazing base, but it is still hard for the average user to customise, which is why OpenMedia provides myPVR fully configured. As to where it is going, lots of interesting work in the digital TV space is where we are playing catchup to MediaPortal. Also, there's some nice work in the IPTV space, but we always will be hindered by the proprietary DRM solutions on the market. Commercially, the biggest gap right now is the lack of Blu-ray and HD-DVD support. I have to be

FEATURE OpenMedia myPVR 2.0

very careful about any statements I say, as I don't want potential customers assuming support.

JH: Do you think this is going to be a big issue for MythTV and myPVR?

SE: We have to keep up with the technologies. We showed off myPVR at Auckland's Big Boys Toys show last year, and the feedback was awesome, but a lot of consumers assumed it would already have HD-DVD or Blu-ray. Geeks usually can get by with the technology at hand.

I think that DRM and potential legal issues are a bigger risk to MythTV, and myPVR. The pending changes to the New Zealand Copyright bill will make myPVR effectively illegal.

JH: What changes are those?

SE: The law finally makes time shifting legal, which is great, but some of the rules and provisions are simply idiotic. For example, you can time shift only material that isn't available "on demand". How are you supposed to police that?

It also provides a lot more weight to the providers of DRM. They capture most of this under TPM (Technological Protection Methods). It becomes illegal to remove, tamper, reverse engineer or study TPM except for a couple of exceptions. Where it really hurts is that it becomes illegal to provide, produce or sell equipment or software capable of removing TPM. That hits us hard, as DVD playback on Linux is effectively TPM removal.

JH: Yeah, that's pretty rough.

SE: Plus, we might be required to enforce the restrictions on time shifting. For example, our units would not be allowed to keep material for more than a reasonable amount of time, but there is no definition of what a reasonable amount of time really is. Days, weeks, months? There also is a provision for format shifting of audio, but not video or pictures. Hence, we shouldn't allow our customers to copy their old VHS tapes to HD or DVD, as that is breaking the law. They are pushing the policing to the equipment providers.

Overall DRM is a potential killer for nonproprietary devices like MythTV.

JH: I'm assuming this is the same in the US as well?

SE: Consumers would love a one-device-fits-all product, but with the advent of competing DRM systems for IPTV on top of the DRM used by traditional pay TV companies, there is a lot of lockout. At least some of the US cable companies provide cable boxes that do the DRM that have FireWire connectivity for PVRs to hook into. Then, there is the DRM in the audio space. Consumers just get annoyed when their iTunes tracks don't play on their Zune, etc.

JH: It all sounds pretty bleak really for Linux PVR devices.

SE: All PVR devices. Microsoft has similar issues with Media Center. But,

It also includes a music player interface capable of ripping, encoding, sorting and playing most popular audio formats, with nifty full-screen visualisations.

as shown in the UK and parts of Europe, there is a large market for FTA (Free to Air) services. We are finally starting to transition to FTA digital here. Thankfully, New Zealand is going for a third-generation digital terrestrial system based off H.264 rather than the bandwidth-hungry MPEG-2 HD you get in Australia and the US. One of the greatest strengths of MythTV is the global development. The support for the HD tech we will use here already has been written and tested by guys in the UK.

JH: Are there any good open-source alternatives to MythTV?

SE:MediaPortal is open source but on Windows. Some people love Freevo,

but it is more of a wrapper around existing tools, rather than an integrated solution. The Elisa work from the Fluendo guys also is really interesting (elisa.fluendo.com). At the moment, their focus has been on playback, but when they have the PVR features, it could be a real killer app.

JH: So, what else would you like to share about myPVR before we wrap this up?

SE: A couple odds and sods....

We try to contribute back where we can—for example, support for the New Zealand MHEG profile for digital interactive TV in both MythTV and the external RedButton application. All the work has gone back to the community. It's not a lot of code, but there was a hell of a lot of testing. Plus, we had full support the day the Freeview network launched in New Zealand. Another area we got involved in by accident was a user interface for a customer with cerebral palsy (www.mythtv.co.nz/mythtv/remote/remote-wide.html).

He can't use a normal remote control, but has a special keyboard/mouse. With this Web remote, he can use all of the features of his PVR.

JH: That's a very cool example of the flexibility of open-source software.

SE: Yeah. He helped iron out the niggles and just loves the way it works. Finally, we were originally based on KnoppMyth, but we currently are collaborating with the Mythbuntu team to get some of the tricks we've learned included in their build.

JH: Thanks for your time.

.....

myPVR 2.0 is a pretty polished product given the limitations of the platform. It doesn't diverge far from standard MythTV, but what it does do is put together a solid product that saves you many hours of pain attempting to configure it yourself. We give it a thumbs-up and look forward to seeing how it improves with Mythbuntu. ■

LINUXWORLD⁰⁷

CONFERENCE & EXPO

23-24 October 2007 • Olympia 2 • London

Open for business

LinuxWorld Conference & Expo2007 is the premier event focusing exclusively on Open Source and Linux technologies. The show, which attracts technical decision makers and business professionals will showcase the latest technology, debate the use of Open Source in the desktop environment, touch on the use of Linux in the datacentre and discuss the development of a common Linux-based platform for mobile phones.

Conference

Attend the groundbreaking conference, where you can see world leading technical experts discuss the industry's more relevant topics. Aimed at technical and business professionals, the 2007 conference will offers:

- 2 full days of content, covering many fields
- 2 conference/masterclass streams
- Indepth technical sessions
- Business focused seminars

Book your place now by registering at www.linuxworldexpo.co.uk

Expo

As well as being able to visit over 60 exhibitors, showcasing new products and services, the Expo offers wide reaching benefits to you, the visitor:

- On the floor business briefings, showcasing real life examples of advantages, applications and integration of Linux and Open Source in the business
- Great Linux Debate
- Take LPI Examinations at a special visitor discount
- Meet developers and technical experts in the .org Village

Register now for free entry at www.linuxworldexpo.co.uk

Getting Started with the Trolltech Greenphone SDK

Everything you need to know to start
programming for the cool new Greenphone.

ROBERT E. HARTLEY

Trolltech recently released many smartphone developers' dream combination—the Linux-based Greenphone and its open-source Qtopia Phone SDK.

The Trolltech Greenphone is a full-featured tri-band GSM (900/1800/1900MHz) mobile phone with a built-in 1.3 megapixel camera. Like many other modern smartphones, it features a QVGA touchscreen, Bluetooth, client USB, mini-SD Flash and stereo audio connectors.

Under the hood, it is built around a Marvell 312MHz PXA270(ARM) processor, runs with 64M of RAM, and has 128M of built-in Flash storage. It also uses the same field-proven Broadcom BCM2121 GSM/GPRS baseband processor module as the Palm Treo.

The Greenphone almost could be described as a sporty, Linux version of the Palm Treo. It is much lighter, more compact and comes in any color you want—as long as it's green!

Introducing the Qtopia Greenphone SDK

The Greenphone SDK is a distribution of Qtopia Phone Edition, specially configured for use on the Greenphone. Qtopia (formerly Qt Embedded) inherits its API from Trolltech's flagship product Qt, a mature C++ application framework available for Linux/X11, Windows and Mac OS X. Qtopia is specifically enhanced for embedded Linux devices, such as phones, PDAs and appliances.

Qtopia is remarkably self-sufficient—sitting immediately on top of the base operating system, it provides its own font and image rendering, window management and input processing. Along with this sort of behind-the-scenes stuff, Qtopia avails itself of all the rich features of Qt's standardized access to files, networking, multithreading, internationalization, graphics processing and, of course, GUI widgets.

Like its big brother, Qtopia is readily available either as a free download to those wanting to do GPL-style open-source development or by commercial license purchased from Trolltech.

Qtopia also bundles a suite of personal information management tools as would be expected on any PDA or smartphone.

Inside the Box

When you open the Greenphone's box, you find everything needed to start developing: mobile handset, power supply, USB cable, stereo headset and a Greenphone SDK CD-ROM. This last item contains a copy of the VMware player and a virtual machine preloaded with Debian Linux, Qt, Qtopia, KDevelop, native development tools and a complete ARM cross-compiling toolchain.

Figure 1. Greenphone Package Contents

Gnokii

For an excellent example of a Linux program using GSM AT command codes, check out Gnokii—it's a great tool for learning about GSM modems, as you actually can watch each transaction with the data sent and received to execute commands to dial the phone, send SMS messages and so on. It works well with most modern phones that have a serial or USB data connector. By the time this article is printed, it might already be running natively on the Greenphone. For complete details, visit www.gnokii.org.

The only other item needed actually to go on air with your newly created applications is a GSM subscriber identity module (SIM) card with a currently active account.

What Is GSM?

The two most widely used standards for cellular communications are GSM and CDMA, with GSM outnumbering CDMA worldwide by a ratio of about 1 billion to 270 million users. Although they are as completely incompatible on each other's networks as AM and FM radio, a normal user typically would notice only that phone accounts on GSM phones are usually tied to the SIM card, so changing handsets is really easy.

GSM currently stands for Global System for Mobile communications. It is an open standard governed by the nonprofit European Telecommunications Standards Institute (ETSI). GSM allows great interoperability permitting easier international roaming. GSM's other claims to fame are higher digital voice quality; a cheap short messaging service (SMS); multimedia messaging service (MMS) for exchanging images, audio, video and rich-text data; and finally, a general packet radio service (GPRS), often used as an Internet gateway, with billing based on megabytes of data transferred, as opposed to time spent on-line.

The Greenphone actually is based on two ARM RISC processors: a beefy Marvell 312MHz PXA270 acts as the PDA part and communicates to the ARM7-based GSM/GPRS communications controller. This controller is effectively the heart and brain of the phone component. It also acts like a modem and accepts GSM AT-style commands to dial, answer calls, send or receive messages, and other activities typical of a GSM/GPRS communications device.

Standard GSM modem AT commands can be sent to the phone, which execute and then return a response code. These AT commands are analogous to the decades-old Hayes modem commands, but instead of using or programming a string like “+++ATDT16505511676” to dial Trolltech's number 1-(650) 551-1676, we do the same sort of thing with the GSM version of the command set, and the string looks more like “ATD16505511676”.

There are myriad other AT commands for handling everything that the GSM/GPRS phone unit can do. These include setting up the phone and establishing various types of communication, such as voice calls, SMS and MMS, and they can be used for getting information on signal strength, network status and so forth.

For a comprehensive description of these standardized commands, you can download the following documents from the ETSI site:

- » ETSI TS 127 007 V3.13.0 (2003-03), AT Command Set for 3G User Equipment (UE): webapp.etsi.org/exchange/ folder/ ts_127007v031300p.pdf
- » ETSI TS 127 005 V7.0.0 (2007-03), Data Circuit Terminating Equipment (DTE-DCE) Interface for Short Message Service (SMS) and Cell Broadcast Service (CBS): webapp.etsi.org/ exchange/ folder/ ts_127005v070000p.pdf

Qtopia embeds the most commonly used of these commands into C++ class wrappers. The on-line documentation in Qt Assistant describes how to use and enhance these classes in the sections titled “GSM Modem Integration” and “Modem Emulator”.

For testing applications off-line, the Greenphone SDK provides a modem emulator that allows testing software without having actually to join a network and go on air.

Getting Ready

Loading the development environment is simple—run the installation program on Windows or Linux, respond affirmatively to the prompts, and within a minute you will have VMware and the SDK tools, application sources, documentation and binaries installed with an icon on your desktop to start things up.

This makes life really easy for reluctant developers using MS Windows to get into both embedded and desktop Linux and Qt application development.

At the time of this writing, developers using the x86 version of Macintosh OS X can use the Greenphone SDK under VMware Fusion, but they need to copy over the virtual machine's files from another installation; however, this may change by the time this article is published.

Getting Started Building Applications

Trolltech always ships its products with copious documentation and example code demonstrating all common features, and the Greenphone SDK is no exception. For starters, the “Developer Quickstart Guide” shows what needs to be done to build an application with a few one-liners.

First, we start the Qtopia emulator using the Qt Virtual Frame Buffer and a Greenphone skin by clicking on the runqfb icon on

» TIP:

One technique for VM-based cross-platform development is to export your display from the Linux VM to your host machine running an X11 server. This might be the built-in X11 server running locally on your Linux host, Apple's optional add-on to OS X or even Cygwin on a Windows machine. I use screens rotated 90° to allow reading many more lines of code without scrolling, so this trick helps to leave the VM configurations as generic as possible. GUI performance typically is enhanced when the X server is run on the host machine due to the lowest level rendering being shoved off as far down the pipeline as possible—often at the display adapter's GPU. Using this method, it can almost make Windows and OS X feel like a Linux box.

our desktop. This is analogous to an X server for Qtopia, and it provides an exact pixel-for-pixel representation of the program running on the phone.

Then, we start the Qtopia phone environment by clicking the runqpe icon, which then connects to the qvfb process and displays its contents in its virtual screen.

Figure 2. qvfb Running with qpe Running in It

We need to run a script to set our QPEVER and PATH environment variables and to define some functions for communicating to the phone. If building for the x86 version of Qtopia, we would use:

```
./opt/Qtopia/SDK/scripts/devel-x86.sh
```

Otherwise, if building for the actual Greenphone itself, we would choose the cross-compile environment with:

```
./opt/Qtopia/SDK/scripts/devel-greenphone.sh
```

Then, we change to our directories and build:

```
cd ~/projects/application
qtopiamake -project && qtopiamake && make && gph -p -i
```

The qtopiamake program is Qtopia's version of the Qt qmake utility. It can generate a .PRO project file based on the contents of the current directory if given the -project parameter, but its most important job is to use the project file as the starting point to generate a Makefile based on the installed configuration of Qtopia and the type of build we want.

Typically, we generate a new .PRO and Makefile only when we have new files to add to our project, but qtopiamake takes so little

»NOTE:

It might be worthwhile to point out that the commands depicted here are separated by a double ampersand (&&) to cause execution of the command string to stop at the first point where it meets an error. In this case, it would stop the shell from trying to execute or install a program that had failed to build.

gph Utility

The gph utility is a useful awk script that provides convenience functions for doing things like building, packaging, installing and running applications in the Qtopia environment, either emulated or actually on the phone. It can be invoked instead of make, and it is powerful enough that we can use it to convert from raw source code to running applications installed from a package onto a real or emulated device.

For example, to rebuild the code, package it and install and run on qvfb, we would try the following command:

```
gph -C x86 -debug -c -all
```

If that were to go well, and we were happy with enough to want to run it on an actual phone, we could build ourselves a package to install with the following:

```
gph -C greenphone -p
```

This would give us a file in our pkg directory with a name like qpe-application_1.0.0-1_arm.qpk.

To have a more complete idea of the gph capabilities, we can look at its help message:

```
$gph --help
FORMAT: /opt/Qtopia/SDK/scripts/gph <options>

Options:
-h          display command help
-q          quiet mode
-c          clean
-C <opt>   reconfig <x86> or <greenphone>, default greenphone
-b          make
-p          make package
-i          install package to greenphone
-r          run application on greenphone
-all       reconfig, make, make package, install, run
-debug     force configure for debug build, override default
-release   force configure for release build, override default

-options "<opts>" pass extra options to build system
           eg. /opt/Qtopia/SDK/scripts/gph -C x86 -all -options "CONFIG+=debug"

-net       bring up network to greenphone
-console   console on greenphone
-qpk <file> install qpk to SDK http server for installation
-rescan    Tell Qtopia to rescan for new documents and applications
```

NOTE:

As a brief reminder to newer users of Qt, classes generated by Designer do not have a base widget that contains all the other widgets inside it. The code in the generated class instantiates child widgets of only whatever parent widget instance is passed into its constructor. This is a reason why we see multiple inheritance used with classes derived from Qt Designer-generated code—it provides a single widget from which to hang other widgets.

time to execute that it is common to see it run from a standard shell script every time.

When applications are packaged for distribution to Qtopia devices, they reside in .qpk files that are specially made gzip'd tar files. In addition to the executable file itself, there also are the help files, multilingual translation files and the desktop entry. This desktop entry file contains elements to describe the name of the executable, the icon, what type of application it is and, finally, the MIME type to indicate what sort of data it can process.

Debugging on Target

Debugging our application on the Greenphone itself is fairly easy to set up.

First, we need to configure our build environment to cross-compile for the ARM architecture on the Greenphone:

```
./opt/Qtopia/SDK/scripts/devel-greenphone.sh
```

Next, we need to rebuild our Makefile and executables, package them up and install them onto the phone:

```
qtopiamake -debug && make clean && make && gph -p -i -r -debug
```

At this point, we can click the arm-linux debugger icon on the desktop, open the example program on the phone and click run to execute it in the remote debugger.

Building for Development and Deployment

A number of application deployment methodologies are available when developing with the Greenphone SDK.

First, we can build and run our applications so that they execute within the virtual machine's ersatz phone-like environment complete with a JPEG skin that looks like a phone sitting on your desktop. It is great for working out the GUI parts of an application, and it saves us the step of having to compile, flash on to the unit and debug remotely.

Second, applications can be compiled and packaged for the Greenphone, then run and tested on the device itself. As mentioned previously, the VM installs with a gdb debugger that can run inside the virtual machine and debug applications remotely on the phone.

Finally, we have "Phone bounce" mode, using the phone as a standard GSM/GPRS modem connected to the development machine via a USB cable. Our applications would run inside the emulator on the local machine, but would be joined logically to the real phone by whatever network link you have to it, such as a USB connection.

We do not have to customize the Greenphone in a piecemeal fashion. The Flash image representing the whole Greenphone Linux

distribution on the phone can be updated using either the mini-SD Flash reader or the USB cable to re-install a complete new Linux distribution along with all the applications and configuration files. This makes it easier for enterprise use where items such as standard configuration options are set to enable things like corporate branding with visual themes, VPN settings, default address-book entries and localization settings, among others.

Anatomy of a Qtopia Application

Qtopia development will make any Qt or KDE developer feel right at home, as it is quite compatible with the desktop version of Qt. There are a few minor differences, as we will see in the example application in the Greenphone SDK found at ~/projects/application.

The style lately, with C++ in general and Qt v4.x in particular, is to include a header named after the class we want declared. This saves ever having to guess which header contains a class' declaration. In the following example, we have the old way commented out and the easier-to-remember method following it:

```
// main.cpp
#include "example.h"
// #include <qtopia/qtopiaapplication.h>
#include <QtopiaApplication>

QTOPIA_ADD_APPLICATION("example", Example)
QTOPIA_MAIN

// end of main.cpp
```

The function formerly known as main() has been deprecated in Qtopia in favor of two macros.

In the above example, the QTOPIA_ADD_APPLICATION macro is used to create an instance of the main application window. The first parameter is the executable name, and the second parameter is the base class of the application window class.

The QTOPIA_MAIN macro expands out either to the traditional main() function if building a traditional application or to the entry point needed if building a quick launcher plugin.

Inside our example.h, we find the class declaration for our main window, which we have sub-classed from a generic QWidget:

```
#ifndef EXAMPLE_H
#define EXAMPLE_H
#include "ui_examplebase.h"

class ExampleBase : public QWidget, public Ui_ExampleBase
{
public:
    ExampleBase( QWidget *parent = 0, Qt::WFlags f = 0 );
    virtual ~ExampleBase();
};

class Example : public ExampleBase
{
    Q_OBJECT
public:
    Example( QWidget *parent = 0, Qt::WFlags f = 0 );
    virtual ~Example();

private slots:
```

```

void goodBye();
};

#endif // EXAMPLE_H

```

This class uses a form created using the Qt Designer GUI building tool, so we see an include file called `ui_examplebase.h` that brings in its declaration. In Qt, headers with names starting with `ui_` typically are Designer-generated. This is followed by our class' immediate ancestor called `ExampleBase`. This base class inherits from both `QWidget` and the class defined by the GUI builder called `Ui_ExampleBase`.

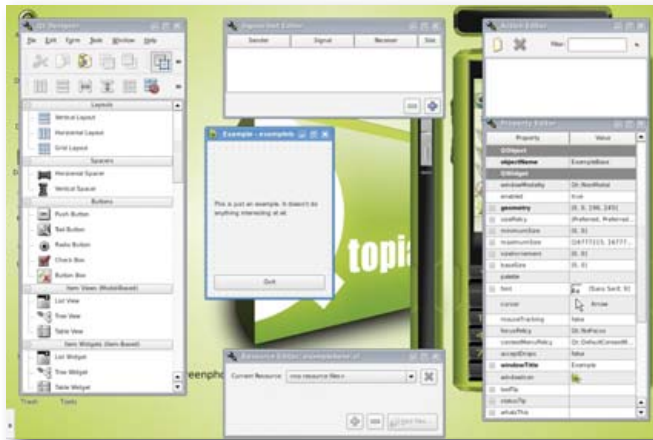

Figure 3. Designer Running in VM

Our main window is an instance of the `Example` class derived from `ExampleBase`. It makes use of a technique called signals and slots—a method used by Trolltech that allows great flexibility for defining how a function is invoked. The invoking side of the connection is called a `SIGNAL()`, and the invokee side is called a `SLOT()`. They are joined together using a method called `connect()` that allows a many-to-many connection relationship. Qt uses a preprocessor to add metadata processing to add to C++ dynamic invocation and object introspection effectively and elegantly—elements available in other OOP languages.

Our final code example shows the implementation of our classes:

```

#include "example.h"
#include <QPushButton>

ExampleBase::ExampleBase( QWidget *parent, Qt::WFlags f )
    : QWidget( parent, f )
{
    setupUi( this );
}

ExampleBase::~ExampleBase() { }

Example::Example( QWidget *parent, Qt::WFlags f )
    : ExampleBase( parent, f )
{
    connect(quit, SIGNAL(clicked()), this, SLOT(goodBye()));
}

Example::~Example() { }

```

```

void Example::goodBye()
{
    close();
}

```

Our `ExampleBase` class' constructor calls the Designer-generated `setupUi()` method to have the form-defined child widgets created and their layout and other properties set. Without that step, it would be a generic `QWidget`.

The next interesting thing we see is the constructor for the `Example` class. It calls the `connect()` method to join the `clicked()` signal on the Qt Designer-generated `QPushButton` called `quit` with our `goodBye()` slot. This allows us to exit the example program by clicking the `QPushButton` labeled `Quit`.

Where to Go from Here

It would be great to explore many other Qtopia-specific features in more detail, such as the `QCop` IPC mechanism for communication across processes, the XML-based theming engine, the secure execution environment (SXE), plus all the phone-specific features, for starters.

Qtopia provides a lot of advantages for the embedded developer designing applications for mobile phones.

Besides the emulation environment, the code compatibility with desktop applications and the natural intuitive application framework, I find that Qtopia does something better than other embedded environments do—it helps put the fun back into programming. ■

Robert E. Hartley is happily married and the father of four wonderful children. He is a dual-national Australian/Canadian living in Ottawa, Canada. Robert started his working life as a programmer writing assembly language on IBM mainframes before getting hooked on UNIX and C in the mid-1980s. He started using Linux as his principal desktop environment ten years ago, and has until recently been busy consulting and training customers around North America and Europe as a Trolltech certified Qt Trainer for its North American training partner, ICS (www.ics.com).

KDENLIVE

Is a Promising Work in Progress

KDENLIVE is the Kracker-Jack video editor with the Kantankerous name.

Dan Sawyer

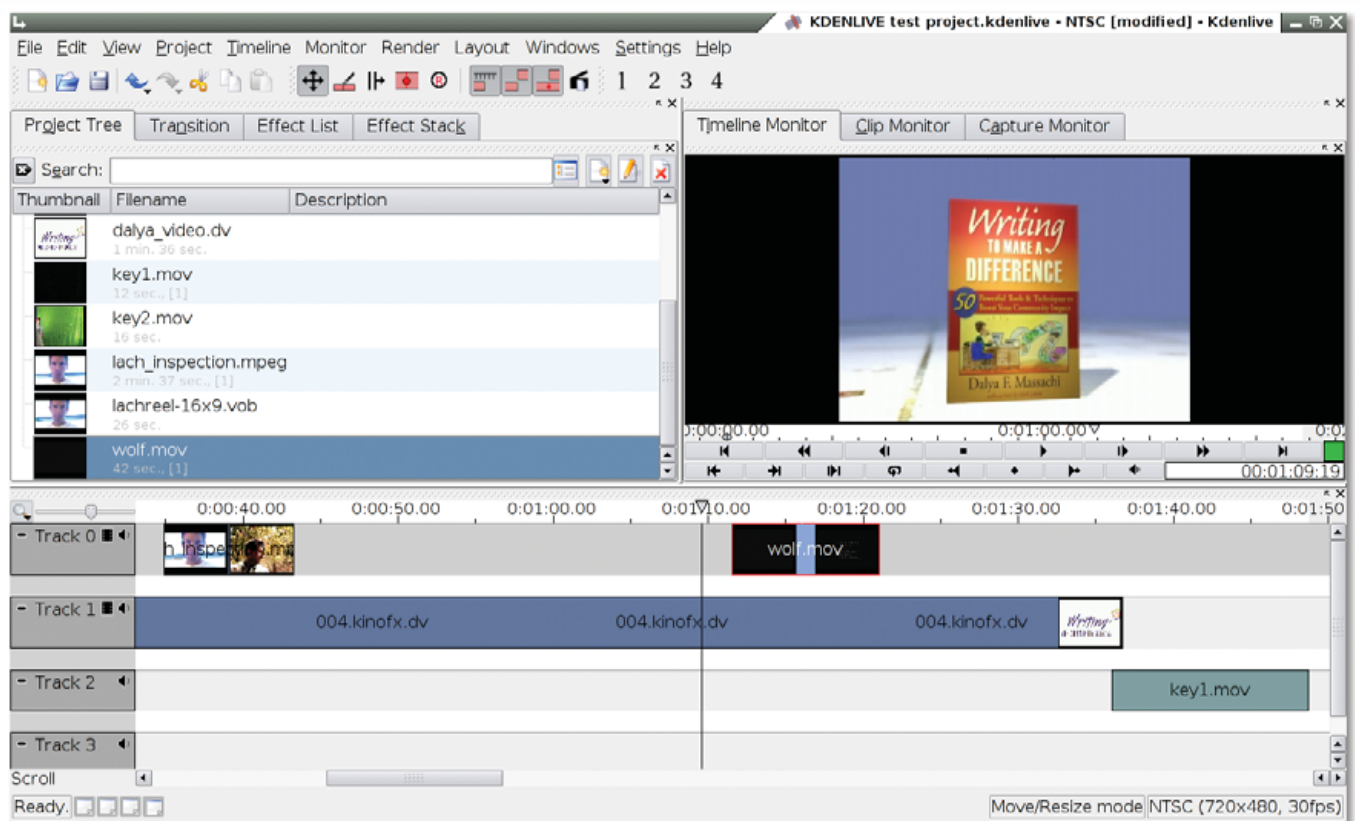

Figure 1. Manipulating the Project Tree in KDENLIVE

I had a stage play to edit. I didn't shoot it, and that lack of quality control on the head end meant that the editing was not the straightforward matter it should have been. It was shot in HDV, which is stored as an MPEG-2 transport stream, and my normal editing program doesn't play nicely with MPEG-2. Because it was a rushed job, I didn't have time to pull

in a developer to add HDV support to it. So, I was faced with the task of turning around a difficult edit on a short timetable, using footage in a file format my favorite editor couldn't read.

Fortunately, this is open source. And, the odds are that somewhere, someone has run into the same problem before and done something about it. In this case,

my friend Dan Kennedy (developer of Kino) pointed me to a new video editing project named KDENLIVE (yes, it really is an acronym: the K Desktop Environment Non-Linear Video Editor), which is based upon his multitrack engine MLT (Mutton, Lettuce and Tomato—the XML file format it writes to, appropriately enough, is called Westley).

I had run across KDENLIVE before, but had run away just as fast. Yes, Virginia, there *is* a hell. And, it's a very special hell, more heinous than that reserved for child molesters and people who talk at the theater, grander than Dante's ninth circle reserved for the Borgia dynasty of Popes, with more exquisite torments. This tenth circle, invented in the digital age, exceeding any that came before it, is the bane of Linux users everywhere, Dependency Hell!

This special torture is reserved especially (though not exclusively) for those of us intent on bending the mighty Linux dragon to our will, forcing it to perform feats of derring-do in the creation of art. Occasionally, in this never-ending struggle to do with open source what people with bigger wallets do easily on a Mac, the erstwhile adventurer stumbles upon a tool, just on the point of maturity, suitable to be appropriated to the task at hand.

This time, I didn't have the option to run away from KDENLIVE. Blender wouldn't do—the Video Sequence Editor doesn't perform well enough on my machine to edit HD with real-time playback. Cinelerra wouldn't do—a program that crashes every few mouse clicks isn't my idea of fun. I could have done it in Kino, but that would make for nightmares conforming the audio later, as I'd have to patch it up manually in Audacity when the video cuts had to jump in the middle of a word (not to mention the necessity of converting to DV beforehand, which meant chewing up another 200GB of hard-drive space I wasn't keen on parting with).

None of the other projects on the radar looked like they offered any significant advantage over KDENLIVE, so I bit the bullet and downloaded the thing, steeled with a vial of holy water for my descent into that very special Dependency Hell.

I started working my way through the list and...everything worked. The install was almost flawless, aside from a couple tweaks that had to be made to the MLT build parameters to accommodate a 64-bit environment. Within about an hour (and that spent building the extensive list of dependencies from source), I was up

Stacking up against previous open-source forays into multitrack editing, KDENLIVE shows definite areas of improvement.

and running.

Well, running might be overstating it a bit. This was KDENLIVE version 0.4, and it was dog slow. To bisect a clip, the work flow went like this:

1. Select razor tool.
2. Choose cut point.
3. Click on the cut point to make the cut.
4. Go into the kitchen, pour a fresh glass of iced tea.
5. Come back 45 seconds later just in time to see the cut update to the interface, and continue working.

No, I'm not exaggerating for comic effect.

This clearly was not going to work. I couldn't bill my client for time spent on a laggy interface, and I didn't much relish the thought of spending several orders of magnitude more time on the project than I could honestly bill for. As a last-ditch effort before borrowing a Final Cut HD machine for the weekend, I gave the KDENLIVE SVN version a try.

This one worked. It was still a little slow, but it was certainly serviceable. It played the HDV back in real time, and its lack of an HD edit profile, while annoying, was not a deal-killer as my client wanted a standard-definition DVD as the end product.

A Multitrack Editor

KDENLIVE presents itself pretty much as a standard multitrack editor—its interface looks similar to versions of MainActor and Premier from years past. All visible and within easy view in nested, dockable tabs are as follows:

- » An asset management window.
- » Effects control dialog with the standard crop of basic transitions.
- » Clip selection, timeline and video capture viewer ports.
- » A multitrack a/v timeline supporting infinite tracks.

Stacking up against previous open-source forays into multitrack editing,

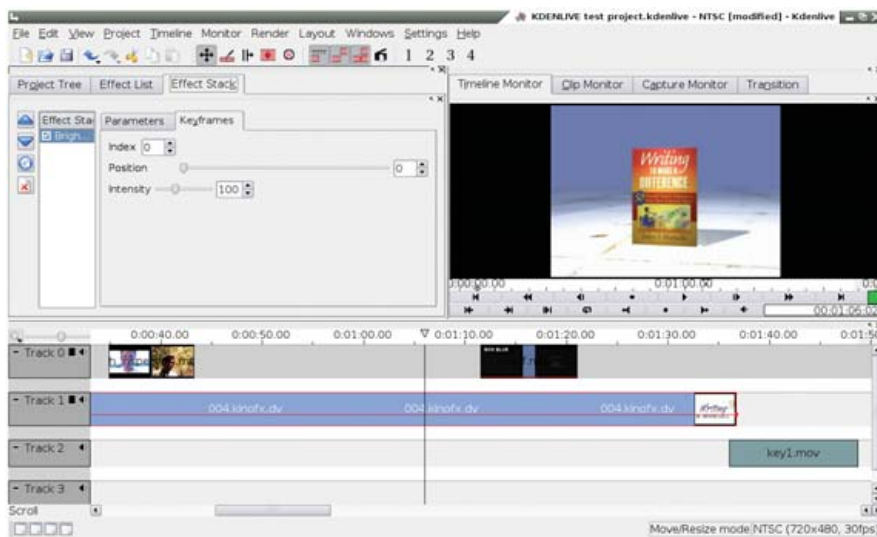

Figure 2. Adjust Effects through Keyframes

KDENLIVE shows definite areas of improvement. It is the only NTSC-capable multitrack editor besides Cuisine (not currently maintained) that is suitable for doing long-form projects in Linux (at least, without plopping down upwards of \$15k for a used Discrete Smoke workstation). To date, I've used it on three long-form projects, and the hours spent in front of it have been more than enough to shake out its better and worse points.

On the credit side of the equation, it doesn't seem to suffer from the sound-sync problem introduced by unlocked DV audio (a format that is, mercifully, beginning to ebb away as HDV with its constant bit rate audio replaces it). In most open-source editors (and some commercial ones), the slightly variable sampling rate of DV audio was enough to cause gradual sync slippage, running into several seconds of slippage over the course of an hour-long DV tape. Good DV editors, like Kino, had internal resampling that kept things on track in the editor, but upon format conversion for a DVD, the sync problem would show up in spades. Kino fixed this problem by integrating audio locking upon export. Although KDENLIVE does not obviously do this, it nevertheless seems not to suffer from this problem—or, if it does, I haven't detected it yet.

KDENLIVE's variety of export profiles also is worth cheering about. Presets (customizable) for most conceivable end formats are here, from Flash to H.264, from DV to DVD—a full range of standard-definition and Web profiles is here for the asking. The list of importable formats is no less impressive; because it uses FFmpeg for its encoding and decoding engine, it imports anything FFmpeg can read. This alone places KDENLIVE near the top of the heap for format compatibility.

Finally, the list of available video effects and transitions, although limited, are well implemented and have sensible, accessible interfaces. The maintainers' determination to make a program that "just works" shines through in many areas, even at this early beta stage.

A Work in Progress

On the other side of the scale, KDENLIVE underperforms because of its unfinished status and some basic design oversights. The first set of issues will doubtless be fixed in future revisions, but the second are things not yet on the road map, or they are out-and-out software bugs. In the

first category, the lack of high-definition profiles is a significant drawback; however, it is rumored that the next release of the software will fix this issue. The ability to create videos from still image files is non-functional at the moment due to a software bug, and the titler, while fully implemented, suffers from the same bug and thus doesn't actually create titles that show up in the viewer windows. The performance on the current SVN version, although respectable, is still sluggish enough to be irritating, and it could use some interface optimization.

In terms of major oversights, three come readily to mind. The audio fader envelopes are not directly editable on the timeline, but may be accessed only through the effects control interface—a situation that is cumbersome at best. The faders are limited further by the ability to

KDENLIVE's variety of export profiles also is worth cheering about.

insert only two keyframes in any given clip, so doing something as simple as a fade-out at the end of a clip necessitates slicing off a separate clip solely for the purposes of fading out—a definite workflow impediment. Other effects suffer from similar limited keyframe-ability.

Another oversight is the lack of deinterlacing in the scaling workflow. This is significant when switching between resolutions and between aspect ratios in a single project, as if one does not deinterlace before down-scaling interlaced footage, significant unattractive artifacting results. At the moment, for example, the only way to edit interlaced HD footage is to convert it to a deinterlaced high bit rate H.264 before importing it into KDENLIVE. The same rigmarole is necessary for working with interlaced 16x9 SD footage. Although AVIDemux does this handsomely with HD footage, it's an incredible waste of time waiting for the computer to chew down *all* the raw footage rather than implementing deinterlacing into the output workflow as a check-box option. AVIDemux does not work on raw DV footage at all, so when working in

standard-definition DV, one has to resort to hand-converting things on the command line or on (shudder) a Windows machine.

Finally, nondestructive exporting does not seem to be implemented yet. In experiments I conducted with regular DV footage pushing through KDENLIVE, there was a noticeable quality drop between the footage I started with and the footage I wound up with at the other end of the pipeline. Dan Dennedy suggests to me that this may be a limitation with the underlying MLT framework, but the digging I've done seems to indicate that the output is handled by FFmpeg scripts rather than by MLT. If this is indeed the case, tweaking the scripts should be all that's necessary to correct the problem.

Other than those fairly obvious weak points, the only major drawback with KDENLIVE boils down to a failure of imagination on the part of the interface design. The layout of the screens is entirely conventional and fails to leverage some of the more interesting innovations made by other open-source multitrack projects, such as Cuisine's multicamera track-switching paradigm and OpenMovieEditor's clip bin asset management strategy. KDENLIVE is building a solid base to work from, but as it grows, it should not neglect borrowing effective innovations from other open-source projects.

In sum, KDENLIVE is a stable, usable multitrack editor that holds up well under the weight of long-form projects, so long as proper prep work is done to conform the footage before editing. Even though in beta stage, it's worth adding to one's toolbox and using often. Its limitations are significant, but forgivable at its current stage of development. Although not suitable for every project, it is ideal for long-format shows with basic editing needs. Hopefully, as it grows, it will expand its horizons and pilfer the good innovations of other nascent projects, and give us finally a powerful editing system suitable for a wide range of projects. The developers of this program deserve a pat on the back and a friendly beer, and hopefully perceive before them a wide vista for the future of their project. ■

Dan Sawyer is the founder of ArtisticWhispers Productions (www.artisticwhispers.com), a small audio/video studio in the San Francisco Bay Area. He has been an enthusiastic advocate for free and open-source software since the late 1990s, when he founded the Blenderwars filmmaking community (www.blenderwars.com). Current projects include the independent SF feature *Hunting Kestral* and *The Sophia Project*, a fine-art photography book centering on strong women in myth.

Interview with Bob Sutor

IBM's Bob Sutor opines about open standards, open source and how best to use software patents. GLYN MOODY

Bob Sutor studied mathematics at Harvard and Princeton before joining IBM Research in 1982. His exploration of ways of exchanging documents containing mathematical formulae so that they preserved their functionality led him to become active in the then-new field of XML. After a stint working on Web services and IBM's WebSphere family of application servers, he became Vice President, Open Source and Standards, in January 2005.

GM: When did you first come across free software?

BS: It was back in the mid-1990s. I was in IBM Research for 15 years, in the Math department there, and we had produced something called techexplorer, a plugin for Netscape Navigator that let you see [the results of the typesetting systems] TeX and LaTeX. We had come to the conclusion that we weren't going to get decent built-in math support in the browsers. In fact, this was the first Netscape plugin IBM ever produced, so it was kind of new and wild.

As we wanted to move beyond a Windows implementation, we started looking at GCC. So we started trying to understand the intricacies of GPL, as it was back in the mid-1990s, and what exactly the rules were. [There were] some very, very early exchanges with Richard Stallman, just trying to figure out what this thing was and what was allowed. We maintained a fairly rapid e-mail exchange back and forth, until he felt I understood the situation.

It was before IBM made its big push into Linux and made any sort of formal announcement, as we did a little bit later in the 1990s. I was a mathematician, who was doing a lot of software development. I certainly understood commercial software, but [free software] wasn't a deep philosophical stretch for me, coming from mathematics; I had never charged anybody for a lemma or a corollary. So it was very much trying to figure out how that fit into the IBM world, which at that point was completely commercial, traditional, proprietary software.

GM: When you became Vice President, Open Source and Standards, in January 2005, what did that involve?

BS: Initially, a lot of it was around internal transformation. IBM is a very big place. We can tackle aspects of the same problem in many different parts of the company. And so when it came to standards, particularly things like industry-specific standards, we did a lot of work there to tie together the different parts of the company, to do the right thing in a very coordinated way.

I have had, since I left research, a fairly vocal position. For example, when [the international standards body] OASIS really kicked in around 1999 or so, I was on the first board of directors there. I had been used to making a lot of noise, if you will, externally, about standards, about industry directions and so forth. And so in this current role, there are internal management aspects of it, as it relates to standards and open source across IBM, [and] there's also an external role as well.

GM: What is IBM trying to achieve with open source?

BS: From a business perspective, I would give a fairly traditional answer of saying, "Well, it's providing our customers with the appropriate IT tools and technologies to become better businesses." It may sound vanilla, but that really is the ultimate goal.

But then you kind of back up and say, "Well, how do you do that?". You've got potentially a very large number of choices of software and ways you can mix and match them in together. You have traditional proprietary software and you have some open-source options as well. So for us, the business goal is to optimize this hybrid mix of proprietary and open-source software to give our customers what they need.

GM: IBM was one of the first major computer companies to support open source, so why hasn't it followed Sun in pledging to open all of its code?

BS: Well, let me say that Sun will do what Sun feels is appropriate for its business model and its history in the software business, and we will do the same. We will look at where we have successful businesses: if that's around proprietary software we will continue them, if that's what customers want to buy. Where customers want a more hybrid strategy, such as what we've done with WebSphere, we can do that too. If you go and you talk to our folks in the Linux Technology Center, they are just totally open source.

We have the breadth that we don't feel that we have to just make some overarching, universal statement. We have a number of business models, some of which are traditional, some of which are completely open source—and increasingly, they're a combination of the two. So we do what works and, we hope, what our customers need us to do. Maybe something else works for Sun, but that, at least, is what's working for IBM. We're very willing to change these in different ways over time.

GM: So if you thought you could serve your customers better and still make a profit, would you then be happy to make everything open source?

BS: Well, I want to get away from this "everything open source", because I'm afraid people will extract just snippets of that discussion. We are doing more open source in 2007 than we did in

ASA COMPUTERS

The Expert on Customized Servers!

www.asacomputers.com
1-800-REAL-PCS

Hardware Systems for the open source community - Since 1989.

(Linux, FreeBSD, NetBSD, OpenBSD, Solaris, MS etc.)

The AMD Opteron processors deliver high-performance, scalable server solutions for the most advanced applications. "Runs both 32-and 64-bit applications simultaneously".

Your Custom Appliance Solution!!

"Let us know your Needs..."

"We will build you a Solution..."

AMD Opteron(TM) Value Server Starts at \$847

- 1U 14" Deep 260W.
- AMD Opteron 140 CPU.
- 512MB PC 3200 DDR ECC Unbuffered.
- Support upto 8GB DDR RAM.
- 40GB SATA Hard Disk.
- 2x 10/100 Mbps Lan.

Quad AMD Opteron(TM) Server Starts at \$2,812

- 1U AMD Opteron Model 840.
- 2GB Memory. Max 128 GB
- Supports upto 64GB FBDIMM.
- 80 GB SATA II Hotswap Hard Drive.
- 2x Integrated Dual 10/100 LAN.

Dual AMD Opteron(TM) Storage Starts at \$4,120

- 5U Dual AMD Opteron Model 246.
- iSCSI or NAS Software Options.
- Support upto 18TB of Storage.
- Fail Hard Drive LED Indicator.

Dual AMD Opteron(TM) Storage Starts at \$8,445

- 8U AMD Opteron Model 246.
- 4TB of Storage (36TB Max).
- 1GB RAM
- 2 x 10/100/1000 Gigabit LAN.
- NAS or iSCSI Software Options.

Why Do Business With ASA?

"We Provide Approved EVAL Server..."

Since 1989, ASA has served customers like Cisco, Juniper, Caltech, Fermilab and most Universities. We provide a total custom solution with OS of your choice.

Excellent pre and post-sales support.

"Reliable hardware at the most competitive prices".

Please call or contact us for your next hardware purchase.

2006, let's put it that way. And as we figure out how to serve our customers, we will go with that.

IBM changes. What one considers IBM today, may change tomorrow. We do acquisitions, for example. We change our business models. We change our mix of what we offer customers, on a fairly constant basis. So I don't want to make one such strong statement. But let me say that if it makes good sense to get more involved with open source in certain areas, we have not been shy to do that in the past, and I don't anticipate our being shy to do that in the future.

GM: Another important area of your work involves the OpenDocument Format (ODF). Where does ODF fit into IBM's overall strategy?

BS: Well, there are two levels. On one hand, you can look at the very practical problem of interchange of information, as represented in office suite data formats. It's nice to represent them in XML; it's even better to represent that information in good, well-designed XML. What this means is that we get full fidelity of exchanging information between applications made by different people. They could be proprietary, they could be open source.

The other aspect is that the fundamental model of how information is created and then shared is changing radically. This notion of a standalone office suite, at this point, is almost ancient in the software world: we've had office suites for well over a decade. To think that we will always use office suites the way we imagined them ten years ago, I think, is just silly, because we are seeing a shift to, for example, on-line applications, software as a service, exchange of information in ways that people never really imagined.

That is, we don't always know who the users of our information are going to be, and we certainly don't expect them to be using exactly the same applications as we are. Indeed, they may not even be people, they may be new computer programs that munch and do very fascinating things with this information. Therefore, breaking loose the data from any particular application that happens to create it so it can be used by any other type of application, I think, is very important.

Now, there's plenty of room for competition there. I don't expect people to completely stop using office suites, of

course. But I do expect that people will simply compete on the quality and the price and the support of that category of software. That is, you don't get to just lock some people in to a particular product category because you happen to have a particular market share at a particular time. You continue to keep your customers by having high-quality products and support at the right price.

If this leads to interchangeability—that is, the ability to use different applications on the same data—that's okay, because frankly, customers like that idea. A vendor or a software provider may not like this idea that you could possibly use somebody else's application, but from a customer perspective, that's pretty good. And, there are more customers than software providers, I may say.

GM: We've seen some pretty interesting things happening around ODF since the commonwealth of Massachusetts standardized on the format in September 2005. What do you think can be learned from that experience?

BS: First, let me say that we have been pleasantly surprised by almost everything that has to do with adoption of ODF. If you look historically, I can't name another standard that's gotten this much attention.

[The] various attempts by people to say that open document standards are a good thing is all progress, because it represents awareness. We went from a situation where people never even thought of this issue to people actively thinking, "Well, yeah, maybe open document formats are a reasonable thing to have."

Massachusetts brought a lot of attention to the issue. It really raised the profile of the importance of information, and who controlled the information. It comes down to a question of the sovereignty of the state of Massachusetts. What happened in 2005, as a result of this discussion around ODF, was this clear separation that said to vendors, "Thou shalt not tell governments what governments can and cannot do with this information." That was a historic turning point in the industry.

It's funny, I had a couple of instances where I've spoken to rather senior people. They've said things like, "We'll have a discussion about ODF", or they'll say, "Well, everyone in my organization uses Microsoft Windows, and they have to use Microsoft Windows and Microsoft Office." And then

right before the end of the conversation, almost as we're out the door, a person will slip in, "But of course, at home I use OpenOffice.org."

What I think this is saying is that people at work in businesses and organizations are still bound by some of their traditional decisions. But a lot of the furor, the discussion around ODF, and [Microsoft's] OOXML, means people are actively looking at this again. And what I'm finding, in a more ad hoc way, is that when these very smart people in positions of power are making decisions about what to do with their own money on their own systems, you know, guess what they're choosing?

And so if you look at any of the things like Massachusetts, or the study bill in Minnesota, or what came up in certain legislatures this year and may come back next year, this is a matter of time. We are all in this for the very long haul. There is not going to be any one event that suddenly makes everyone on the planet use ODF, right? This is just relentlessly incremental, and it's all positive in different ways.

GM: One of the key issues in the open-source world today is software patents. Shortly after you became Vice President, IBM made an unprecedented release of 500 patents to what you described as the patent commons. What was the background to this move?

BS: Well, I got this job at the beginning of 2005. I think the first day of the week was a Tuesday because of the beginning of the year. Someone said, "You're briefing Forrester tomorrow on this patent pledge." And I said, "Oh really? What patent pledge is that?" And, in fact, it had been in the works for a little while.

That was designed to shake up people's thinking about the use of software patents in open-source and proprietary software. It was a way of telling people, "Look, if we can make patents available to the Open Source community, and if maybe they can innovate and take them beyond what we have done with them, and then maybe we could use their results, that's a good thing. This is collaboration. And oh, by the way, no one has done this before; we're trying to figure this thing out too."

That is, whatever you thought of the old IBM and what it's done with its patents, maybe you don't quite know what's

happening here. And, maybe we all need to rethink this. Maybe we are in some type of transition from our traditional view to something new. We're not saying we have the answers. But we're saying that there are a number of things that one can do with intellectual property to accommodate both open-source and traditional software.

GM: Many people, especially in the open-source world, believe that the patent system is seriously broken as far as software patents are concerned. What is IBM's position on that?

BS: In part it's a philosophical issue. I haven't found any stone tablets anywhere that directly say yes or no in terms of patents. So I think it's a fairly social decision as to whether people think they're good or bad. IBM has supported patents, where they are available, for the traditional reasons. But in ways I've described, I think we've been more flexible than almost anybody else in terms of its use.

We wouldn't say that the system is broken. We would say that the system is under a lot of stress. And so it's for that reason we have been working with the Patent Office in the US and other places as well to just generally try to improve the system.

There was in Europe, you may remember, quite a big action around software and patents. And eventually, the bill was dropped because it had so many different things in it. But our position there at the time—and I think we're pretty consistent about this—is that software interoperability is extremely, extremely important. If you look at where we have gone royalty-free, for example—and royalty-free will typically translate to mean there can be open-source implementations—we have basically said that software patents should not get in the way of software interoperability, where it means data formats, where it means protocols and where it means APIs.

GM: On a related note, I wondered what IBM's relationship with Novell was these days.

BS: They're a strategic partner of ours—they were and are.

GM: So what do you think of the agreement Novell and Microsoft announced in November 2006?

BS: Speaking for IBM, we didn't feel it

was necessary. We do not think anyone needs that particular protection from Microsoft. There's never been a successful suit against open source in any way, and so there was no particular need to strike such a deal. If it leads to the greater adoption of open source, the greater adoption of Linux, well, that's probably good for Novell. It's probably good from a partner situation. But we don't think that the world is fundamentally better off because that agreement was made.

GM: Software patents are one of the key areas that GPLv3 attempts to address; what is IBM's view of the new license?

BS: We think they did a great job. We think it was a tough task they set up for themselves. And Richard Stallman and the Free Software Foundation, they opened this up to the community—people who were fervently pro-free software, people in the middle with open source, as well as people who wanted to get involved who maybe didn't like the idea whatsoever.

They completely opened themselves up for a tremendous amount of input from all sorts of groups.

And through all of this, they had to look at the use cases. They had to understand philosophically what they were after and what they could practically get. And we think ultimately they played it pretty well. And so I certainly applaud what Richard's done, Eben Moglen as well, in getting to this [result].

I don't think anyone can deny that all the attention this got fundamentally points to the importance of free and open-source software, and the degree to which it is core to the IT industry today. If no one cared, no one would have said anything. It wouldn't have generated articles in the *New York Times* and the *Wall Street Journal* and *BusinessWeek*. And so, in many ways, free and open-source software has come of age. It's here to stay, and it's part of the mix. ■

Glyn Moody writes about open source at opendotdotdot.blogspot.com.

PEG[®] the leading GUI for Embedded Systems

Prototype Today!
FREE EVALUATION PACKAGE

- PEG+ - Full Featured Windowing in C++
- C/PEG - Smallest Footprint in ANSI C
- Royalty Free
- Fast execution speed
- Completely ROM-able
- Delivered with Full Source Code
- Development Tools including FontCapture, PEG WindowBuilder, and ImageConvert
- Complete set of screen drivers included
- Completely customizable
- Industry leading RTOS Support
- Supports all popular target processors, video controllers and I/O devices
- Multi-lingual support – 2-byte character sets & UNICODE string encoding
- Event-driven programming model
- Application Design Services
- Knowledgeable and timely support to users around the globe
- Now includes a fully licensed version of Paint Shop Pro 9

GRAPHICS SOFTWARE FOR EMBEDDED SYSTEMS

The Ultimate Linux Home

The LinuxMCE Project is a work in progress, promising finally to bring us the Home of the Future. JON "MADDOG" HALL

What started out as an article on the Ultimate Linux Multimedia System ended up being one on the Ultimate Linux Home—coming soon to a home near you, thanks to a project called LinuxMCE. What brought about this change of heart? When I was growing up, I was a big fan of magazines like *Popular Mechanics* and *Popular Science* that constantly talked about the Home of the Future. Such a home would manage lights, turning them on and off as you went from room to room. It also would control heating, automatically adjusting a room's temperature according to whether you were going to sleep, about to wake up or leaving for work.

Figure 1. The Main Menu in the Plainest User Interface (All screenshots in this article courtesy of the LinuxMCE Project.)

The Home of the Future appeared even more frequently in science-fiction books—the home would wrap its arms around you and take care of your every need. It would read books to you and let you answer the telephone without needing to hold a receiver. These services would be available throughout the house, tailored to the occupants' needs.

During the years, such Home-of-the-Future qualities appeared again and again, mostly in concept homes. Small improvements came about through the use of interfaces, such as X10 for remote control of lights and heat, but the promise of anything like the true Home of the Future still seemed far away, except for some with very expensive systems.

About a year ago, I became aware of a project called Pluto (www.plutohome.com), which seemed to pull together elements of other projects, such as:

- MythTV for recording TV programs, photos and music.
- Xine for watching movies.
- Asterisk for handling telephone calls.

It also added security cameras and lighting control, and it tied them all together, controlling them from a variety of hardware, including Bluetooth-enabled phones. Not only that, but it also could "track" you as you walked from room to room and make sure the media playing in the room you were entering was the same as the media playing in the room you just left. You also could access the output of your security cameras from your cell phone and talk through the speakers of your sound system if you wanted to scare a burglar. The Pluto people made a very nice animated video showing how the system would work if it was completely implemented and installed correctly (plutohome.com/index.php?). They also gave a complete listing of all things it could do. It was awesome.

Most important, Plutohome was FOSS! The people working on it encouraged others to join the project and take the code and put it on their own hardware or even to sell systems and services with Pluto software on them. They correctly pointed out that although there were people who would put their software onto "commodity" hardware, there were other people who wanted a complete and tested system, and they were happy to cater mostly to the second group while allowing the do-it-yourself people to use the software and help extend it. Although the functionality was interesting, I did not have the time to look at Pluto further, so I filed it away for future reference.

Then, in March 2007, I heard about LinuxMCE and saw the video on Google Video (video.google.com/videoplay?docid=-4422887272477313460&hl=en).

At www.linuxmce.com, I read that Paul Webber, the founder of LinuxMCE, had been to CEDIA 2006, a consumer audio/video/home-automation tradeshow. There, he had seen a demonstration of Pluto, which by that time had been licensed to Monster. Paul was hooked, but when he was told that Pluto had all it could do to bring this technology to its own customers, Paul decided to work to make it more visible and more flexible for the Free Software community. The interesting part is that he did this with Pluto's blessing and support.

Figure 2. The Same Main Menu, but Using the Most Powerful "Transparent" Interface

At the time of this writing, it is June 2007, and the project Paul thought “would take me a week” has been going on for five months, with Paul and another programmer “working on it almost full time”, but they are approaching a usable version. They have done a lot of work to make it operate on “generic” PCs on top of a “generic” distribution and to make sure users would continue to receive all the device support they needed. Closed, single-purpose systems are not their target.

Today, LinuxMCE is based on the Kubuntu distribution, with Aaron Seigo of KDE pledging to integrate it even better. The goal of the LinuxMCE team is to have additional distributions integrate and ship LinuxMCE. Imagine having a multimedia powerhouse as an option on every Linux desktop and notebook, and that every Linux desktop and notebook could optionally provide distributed, integrated multimedia capabilities.

What Distributed, Integrated Capabilities?

LinuxMCE and Pluto are both frameworks that allow various components to be integrated together. Both projects utilize other major components along with a set of libraries called DCERouter (DCE stands for Data, Commands and Events), a general-purpose message router. It can send messages to applications that are “wrapped” in code and receive commands from those applications when they need something done.

As an example of how this works, say a call comes into Asterisk while you are watching TV. The Asterisk program could send a message to MythTV to mute the show or even halt the show until the call is finished.

Of course, it is one thing when you think about programs controlling other programs, but if you apply almost the same logic to hardware devices, you more easily can map the functions of many home automation products into the framework of the system relatively effortlessly.

The framework also manages plugins, like a lot of other flexible FOSS code (GIMP comes to mind), allowing more modules to be added for new functionality.

Now, let’s look at the different components that make up the system hardware.

The Core

The core is a server that can sit in an out-of-the-way place, such as your cellar or garage. The core is the place where the software and

data are stored. It should have two NIC cards: one for the internal network (recommended as at least 1GB) and one to go to the outside Internet (could be 10/100Mb). The core also should have an interface card for any existing telephone lines that you have (if you have any), for this also is the place where the Asterisk PBX is going to be managing your VoIP telephone calls. Alternatively, you could have a VoIP gateway at some other place in your network.

The core should be a machine where you easily can add disk drives and probably have larger amounts of memory, depending on the load.

Media Director

The media director hooks up to your TV and audio/visual equipment. It can have inputs from your cable boxes or over-the-air connections, CD and DVD drives, audio input, digital “film”

Figure 3. A File Browser in the Plainest User Interface

and other connections to amplifiers, TVs, recorders and so forth. There should be one media director for every room where you would consider having an “entertainment area”.

These media directors typically do not have any local storage. They boot PXE over the network. This allows you to use a PC for the media director and have an operating

Figure 4. A File Browser in the Most Powerful “Transparent” Interface

system stored on the local disk. Boot off the disk, and the operating system comes up. Boot over the network, and it becomes a media director.

However, you also can install both the core and the media director software on your hard disk and start that software at any time. This hybrid allows you to boot into LinuxMCE, then stop the MCE software and use Kubuntu. You also could choose to boot Kubuntu, use it, and then start and stop the MCE software as you desire—very flexible.

Orbiter

The orbiter is a separate system that is just used to control the LinuxMCE system. It can have a touchscreen or use a keyboard and mouse. Orbiters can be a tablet system or even a regular PC, but the function is to control the various parts of the system.

Mobile Orbiter

Symbian Bluetooth-enabled cell phones as well as some Linux, Windows and Windows CE Webpads (such as the Nokia 770), PDAs, Web browsers or even the CISCO 7970 phone can act as control interfaces for the system. As the documentation says, “You can use it [the CISCO 7970] to make calls and control your home as well.”

Symbian-based Bluetooth phones use Bluetooth for communication whenever they can and switch to the cellular data network when users are not close enough to use Bluetooth. If every media director has a Bluetooth connection, you probably will be within Bluetooth range in most parts of your house.

The most amazing part is that the Bluetooth signal also allows the music or video that you select to follow you as you move from room to room. If two people with Bluetooth phones are in the same room, the choice of media stays with the first person who was in the room. If that person leaves, it switches to what the second person had chosen before entering the room. It also can set the lighting in that room, adjust the volume and other functions.

The controls that show up on the various screens are tuned to individual people’s tastes. “maddog” would have a different set of settings, music and preferences than “shedog” (if there were a “shedog”). And, when “maddog” goes to make a telephone call, it shows his own list of contacts. When controlling the system from a cell phone, it shows only the cell-phone owner’s information.

Home security also is managed by this system. You can integrate your video cameras into the system, and if someone breaks in to your house, a live feed sends an image to your cell phone and alerts you. You then can call 911 and make sure the authorities are headed toward your

house or business. You also can speak to an intruder through your speaker systems—much better than a monitored alarm system.

Finally, the core and the media directors actually are general-purpose computers and diskless clients. The core and media directors in your home are joined together as a network, but you also can combine multiple homes with an encrypted VPN. As you go house to house (or across the world), you can access your files and media. Imagine being in your hotel room with high-speed Internet and have access to all your home (or office) data.

All of This Sounds Really Complex

Well, let’s just say that “Mom & Pop”, my world-famous technophobic parents, probably will never set up a LinuxMCE system themselves.

Even if they do manage to get the components out of the boxes, wired and set up, a lot of tailoring still has to be done for the whole system to run correctly. Floor plans have to be inserted, lighting fixtures have to be located, and a lot of data has to be imported or entered to make the whole thing work together.

Fortunately, a very complete and systematic Web server also is built in to the system that lets you set and change almost any facility of the system remotely. In the case of Mom & Pop, once I visited their house, plugged in all of the systems and noted the MAC addresses of all the components, I actually could “tune” the system from my house in New Hampshire (and this is a blessing, believe me). Or, if I were a professional installer of this type of system, I could help customers by tuning their systems remotely.

Now that you are all drooling and asking, “Where can I get it?,” we continue with the rest of the story.

What Types of Hardware Do You Need?

Coming up with the right hardware definitely is half the issue. Building one of these systems from cast-off hardware probably will be less than satisfying.

The CPU probably will be used mainly for encoding and decoding video, particularly if you are interested in high-definition TV. If you have hardware encoders for this, a lot of the work is taken off the main CPU, but if you are using software encoders, you can expect to need about 1GHz of processing power (whatever that means these days) for every stream of video.

Hardware encoders, such as the Hauppauge PVR series, unload quite a bit of CPU utilization and allow a single CPU to encode multiple streams at once. This would be useful if you wanted to record one program while

Figure 5. Playing a DVD Remotely

Figure 6. Dialing a Phone Number

Figure 7. The Security Panel

watching another or record two programs at one time. On my system, it recognized my Hauppauge PVR-150 with no problems.

If you are building the system yourself, be sure to study the LinuxMCE Project's documentation and the pages of MythTV's documentation that discuss hardware.

Status of the LinuxMCE Project

Pluto, as I stated previously, is aimed more at pre-packaged boxes with specialized hardware. The LinuxMCE Project is aimed more toward generalized hardware, with free and open-source software, and it uses no licensed, proprietary software at all.

As such, a goal of LinuxMCE is to be as portable across all distributions as possible, so all distributions can include it. Therefore, a significant amount of work had to be done by the development team, even if the Pluto people helped out a lot (which they did).

The software is now going through testing to put it into V1.1 status, and even though it is only V1.1, the amount of functionality is staggering.

In the beginning, it is prudent to understand that not every peripheral or video card will be supported and to try using only the hardware the testers in the forums have tested and found compatible. However, because the system is using major subsystems that have been around for a while, these projects do support a fairly well-known set of peripherals.

Likewise, some of the installation and integration is not intuitive, even in the second beta test of version 1.1. On the other hand, if you purchase a box pre-installed, this won't be an issue, and at least one company is planning to offer pre-installed and supported systems (the support will be available by e-mail and phone).

Bottom Line

LinuxMCE is a large and complex project, but with a reasonable architecture to allow it to become a staple in the Free Software world. There are still a couple of rough edges, such as a missing editor to allow room diagrams to be inserted into the system easily, and (of course) the ever-necessary step-by-step documentation, but it has huge potential to help make free software more prevalent in the homes of average people.

In my own LUG, we normally have 15 to 20 people show up at a meeting. When we recently had a MythTV meeting, 55 people showed up. LinuxMCE and similar projects move free software and Linux from computers to consumer appliances and make people more familiar with it.

Although LinuxMCE still may not be "baked" enough for most people, I encourage the developers and the readers of this magazine to help move it forward. ■

Jon "maddog" Hall is the Executive Director of Linux International (www.li.org), a nonprofit association of end users who wish to support and promote the Linux operating system. During his career in commercial computing, which started in 1969, Mr Hall has been a programmer, systems designer, systems administrator, product manager, technical marketing manager and educator. He has worked for such companies as Western Electric Corporation, Aetna Life and Casualty, Bell Laboratories, Digital Equipment Corporation, VA Linux Systems and SGI. He is now an independent consultant in Free and Open Source Software (FOSS) Business and Technical issues.

Data Acquisition & Control Computer

iPac 9302

- Cirrus Logic EP9302 ARM9 200 Mhz Processor
- Floating Point Math Engine
- 2 USB 2.0 Host Ports
- SD/MMC Flash Disk Slot
- 48 Digital GPIO Lines
- 1 10/100 Base-T Ethernet port
- 5 channels of 12 bit A/D & 3 PWMs
- 1 RS232 & 1 RS232/422/485 Serial Port
- Battery Backed Real Time clock/calendar
- Eclipse Linux Development Environment

2.6 Kernel

The iPac has enough I/O for demanding applications & with a size of 3.5" x 3.8" it can fit almost anywhere. Prices start at \$150.00. Please contact us for more information.

Stream Control Transmission Protocol (SCTP) Associations

This second in a series of articles on the SCTP network protocol examines associations and connections. JAN NEWMARCH

An **SCTP association** is a generalisation of a TCP connection. Usually a TCP connection is one-to-one between two network interfaces, one on a server and the other on a client. In contrast, an SCTP association is many-to-many in two ways:

- Multiple network interfaces on a server can be associated with multiple interfaces on a client. For example, suppose the server and client both have an Ethernet card and a Wi-Fi card connected to the Internet. Then, data can flow over a single association in up to four possible ways: Ethernet to Ethernet, Ethernet to Wi-Fi, Wi-Fi to Ethernet or Wi-Fi to Wi-Fi.
- An association also can carry multiple logical streams. These are numbered from zero upward. So, for example, stream zero could carry control instructions, while stream one could carry small pieces of data (such as small files), and stream two could carry larger pieces of data (such as an MPEG movie). The three streams are logically independent, so that delays on one stream do not cause delays on any other stream.

Note that a single socket can have multiple associations—that is, one socket can be used to talk to multiple other hosts. In general, these different associations are distinguished by having an association ID. The socket API for SCTP distinguishes between situations where exactly one association can exist (a one-to-one socket) or where a socket can manage many associations (a one-to-many socket). The first case corresponds to the TCP-like case that I discussed in the first article on SCTP [LJ, September 2007]. The second case will be covered in the next article. In this article, I look only at a single association, which is applicable to both the one-to-one and the one-to-many sockets.

Using a Subset of Network Interfaces

TCP and UDP use a single network interface on an endpoint, by specifying its IP address in a `sockaddr` structure. If you specify the wildcard address `INADDR_ANY`, a server will listen on all interfaces while a client will choose only one. In any case, communication takes place only between a single interface on each endpoint. As an aside, if you want to know what all the interfaces on your machine are, use the call `ioctl()` with parameter `SIOCGIFCONF`. How to do this is described in WR Stevens et al., *Unix Network Programming*, vol 1, section 17.5.

Using only one interface reduces reliability when more than one is available. A network cable may have poor connections, or you may be

too far from a wireless access point for a reliable signal. On the other hand, using all of the interfaces may not always be desirable. For example, in Australia, the download charges for 3-G or WiMAX connections are ridiculously expensive, so you would use that interface only if no others were available. Or, a bridge would expose the internal and external interfaces separately to different groups of users.

SCTP allows an application to choose a subset of interfaces on either the source or destination side of an association. Some implementations also will allow interfaces to be added or removed dynamically, so the application can adjust to different states of the network connections. By registering for association-change events (which will be discussed in the next article), one endpoint can track changes in the interfaces at the other end.

The normal socket call `bind()` just takes a single `sockaddr` parameter to bind the socket to a single IP address (or to the wildcard address). SCTP extends this by introducing a new call, `sctp_bindx()`, which takes an array of `sockaddrs` to bind the socket to all of these addresses. The socket is bound only to a single port though; all of the port numbers in the array of `sockaddrs` must have the same port number. And, if addresses are added or removed later, they must have the same bound port value. Otherwise, the call fails.

There is another wrinkle to `sctp_bindx()` regarding IPv4 and IPv6 addresses. The socket can be passed a set of only IPv4 `sockaddrs`, a set of only IPv6 `sockaddrs` or a mixture of both. The two types of socket address structures, `sockaddr_in` and `sockaddr_in6`, have different sizes, so mixing these in the same array can cause alignment issues. SCTP packs the structures together with no wasted space between them. So, you can't just use an index into the array, you have to copy the right number of bytes for each structure and then move up by that amount.

The call to bind a set of addresses is:

```
int sctp_bindx(int sd, struct sockaddr *addrs,
               int addrcount, int flags)
```

where `flags` can be one of `SCTP_BINDX_ADD_ADDR` or `SCTP_BINDX_REM_ADDR`, and the second parameter is a packed list of IPv4 and IPv6 socket address structures.

It is relatively easy to use this on a server to allow clients to connect on any of the server's bound interfaces. But, how do you do this on a client? Where is the `bind()` operation? Well, just like TCP, this is hidden under the covers. In TCP, if a call to `connect()` is made and the socket is not yet bound (the usual case for a client), the TCP stack will choose one of the interfaces and an ephemeral port. You can make an

Listing 1. multi_homed_client.c

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>

#include <netinet/sctp.h>

int main(int argc, char *argv[]) {
    int sockfd;
    int n;
    struct sockaddr_in addr, *addresses;
    int addr_size = sizeof(struct sockaddr_in);
    int addr_count = argc - 2;
    int port;

    if (argc < 2) {
        fprintf(stderr, "Usage %s client-addresses...\n", argv[0]);
        exit(1);
    }

    /* create endpoint */
    sockfd = socket(AF_INET, SOCK_STREAM,
                   IPPROTO_SCTP);
    if (sockfd < 0) {
        perror("socket");
        exit(2);
    }

    addresses = malloc(addr_size * addr_count);
    if (addresses == NULL) {
        perror("malloc");
        exit(1);
    }

    /* do bind to get ephemeral port first */
    addr.sin_family = AF_INET;
    addr.sin_addr.s_addr = inet_addr(argv[1]);

    addr.sin_port = 0;
    if (bind(sockfd, (struct sockaddr *) &addr, addr_size) == -1) {
        perror("bind");
        exit(1);
    }

    /* this gets sin.sin_port so we can find the ephemeral port */
    getsockname(sockfd, (struct sockaddr *) &addr, &addr_size);
    port = addr.sin_port;
    printf("Ephemeral port is %d\n", port);

    for (n = 2; n < argc; n++) {
        addr.sin_family = AF_INET;
        addr.sin_addr.s_addr = inet_addr(argv[n]);
        addr.sin_port = port;

        memcpy(addresses + (n-2), &addr, addr_size);
    }

    if (sctp_bindx(sockfd, (struct sockaddr *) addresses, addr_count,
                  SCTP_BINDX_ADD_ADDR) == -1) {
        perror("sctp bindx");
        exit(2);
    }

    /* get local list */
    addr_count = sctp_getladdrs(sockfd, 0, (struct sockaddr**) &addresses);
    for (n = 0; n < addr_count; n++) {
        memcpy(&addr, addresses+n, addr_size);
        printf("addr %s, port %d\n",
              inet_ntoa(addr.sin_addr.s_addr),
              addr.sin_port);
    }

    /* we don't actually connect to any server in this program */
    close(sockfd);
    exit(0);
}
```

explicit call to `bind()` that will let you choose the interface, but usually the port is left as zero, so an ephemeral port is still chosen.

You can do exactly the same with SCTP—don't call `bind()` and leave it to the SCTP stack. This will choose an ephemeral port like TCP, but instead of using a single interface, it will choose a set of interfaces (probably all that are available). So calling `connect()` without an initial `bind()` or `sctp_bindx()` will give you multihoming on the client side automatically.

If you call `bind()` with a specified interface before `connect()` in the client, you get only that single client-side interface, losing one of the advantages of SCTP! If you call `bind()` with the wildcard address `INADDR_ANY`, SCTP will choose a set of interfaces for you. So, SCTP will try to give you multihoming unless you pin it down

to a single address using `bind()` or to a specific set of addresses using `sctp_bindx()`.

With SCTP, I would expect a call to `sctp_bindx()` with all ports set to zero to choose the same ephemeral port for all addresses. Instead, the current Linux implementation (up to kernel 2.6.21) gets an ephemeral port for the first address and then throws an error, because the ports in the later addresses are still zero instead of this ephemeral value. The workaround is to call `bind()` with one address with port zero, see what the system set the port to, and then call `bindx()` on the remaining addresses with this new port number. Listing 1 (`multi_homed_client.c`) shows an example of this. This workaround probably will become unnecessary in the next specification of SCTP following discussion on the SCTP mailing list.

Listing 2. streamcount_echo_client.c

```

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>

#include <netinet/sctp.h>

#define ECHO_PORT 2013

char *usage_msg = "usage: astreamcount_echo_client ip-addr istreams
  ostream";

        exit(3);
    }

    len = sizeof(status);
    memset(&status, 0, len);

    if (getsockopt(sockfd, IPPROTO_SCTP,
                   SCTP_STATUS, &status, &len) == -1) {
        perror("get sock opt");
    }

    printf("Got: input streams: %d, output streams: %d\n",
           status.sstat_instrms,
           status.sstat_outstrms);

    /* give the server time to do something */
    sleep(2);

    /* no reads/writes are done */
    close(sockfd);
    exit(0);
}

```

Using Multiple Interfaces

You can set the local interfaces to be used by `sctp_bindx()`. A client also can specify the subset of addresses that it wants to use to connect to the server by using the call `sctp_connectx()`, which takes a list of socket address structures just like `sctp_bindx()`. Why do this? Well, using `connect()` with a single address is a possible point of failure at the time that the initial connection is done. This is what the function `sctp_connectx()` solves. It allows the client to try multiple addresses in order to connect to the server.

The set of addresses in `sctp_connectx()` is used just to make the initial connection. But, after the connection is established, an interchange of information takes place between the two endpoints. In that exchange, the remote peer tells the local peer which addresses it actually wants to use and vice versa. The set of remote addresses that the remote peer will use need not be the same as what the client used in the connection. However, you at least can assume that one (but you don't know which one) of the addresses passed to `sctp_connectx()` will appear in the list

that the remote peer offers, because the local client had to connect to something!

So, if the remote peer chooses the set of addresses it uses, how does the local client find which ones they are? This is done by another function, `sctp_getpaddrs()`, that gives the set of remote peer addresses. There is also an `sctp_getladdrs()` function, in case the local peer forgets which addresses it is using!

Once an association is set up between two endpoints, messages can be sent between them. Note that SCTP does not concern itself with QoS (Quality-of-Service) issues, such as real-time delivery, but only with reliability issues. SCTP uses the multihomed capabilities to try as many possible routes as possible to get messages through. So on the sending side, there is no control over which interfaces are used; indeed, the sender might even use a scheme such as round-robin among its interfaces for each message. However, the sending application can indicate to its SCTP stack which of the remote peer's interface it would prefer to use, and it can tell the remote peer on which interfaces it would prefer to receive messages. These are done by using the `setsockopt()` call with option type as `SCTP_PRIMARY_ADDR` or `SCTP_SET_PEER_PRIMARY_ADDR`. Of course, if these particular addresses are not available, SCTP simply will use different addresses in the association.

Once SCTP is told which interfaces to use, it basically looks after things itself. It uses heartbeats to keep track of which interfaces are alive, and it switches interfaces transparently when failure occurs. This is to satisfy the design goals of SCTP for improved reliability over TCP. Applications can give hints to the SCTP stack about which interfaces to use, but the stack will ignore these hints on failure.

Streams

In TCP, a stream is just a sequence of bytes. In SCTP, it has a different meaning; a stream is a logical channel along which messages are sent, and a single association can have many streams. The original motivation for streams came from the telephony domain, where multiple reliable channels were needed, but the messages on each channel were independent of those on other channels. In last month's article, we pointed out some TCP applications that could benefit from streams, such as FTP, which uses two sockets for data and control messages. In addition, an increasing number of applications are multithreaded, and streams open up the possibility of a thread in one peer being able to communicate with a thread in another peer without worrying about being blocked by messages sent by other threads.

The socket I/O calls `read/write/send/rcv` do not know about SCTP streams. By default, the write calls all use stream number zero (this can be changed by a socket option), but the read calls will read messages on all streams, and there is no indication as to which stream is used. So, to use streams effectively, you need to use some of the I/O calls that are designed specifically for SCTP.

Negotiating the Number of Streams

Each endpoint of an association will support a certain number of streams. A Linux endpoint, by default, will expect to be able to send to ten streams, while it can receive on 65,535 streams. Other SCTP stacks may have different default values. These values can be changed by setting the socket option `SCTP_INITMSG`, which takes a structure `sctp_initmsg`:

Linux - FreeBSD - x86 Solaris - MS etc.

Proven technology. Proven reliability.

When you can't afford to take chances with your business data or productivity, rely on a GS-1245 Server powered by the Intel® Xeon® Processors.

Quad Core Woodcrest

2 Nodes & Up to 16 Cores - in 1U

Ideal for high density clustering in standard 1U form factor. Upto 16 Cores for high CPU needs. Easy to configure failover nodes. Features:

- 1U rack-optimized chassis (1.75in.)
- Up to 2 Quad Core Intel® Xeon® Woodcrest per Node with 1333 MHz system bus
- Up to 16 Woodcrest Cores Per 1U rackspace
- Up to 32GB DDR2 667 & 533 SDRAM Fully Buffered DIMM (FB-DIMM) Per Node
- Dual-port Gigabit Ethernet Per Node
- 2 SATA Removable HDD Per Node
- 1 (x8) PCI-Express Per Node

```

struct sctp_initmsg {
    uint16_t sinit_num_ostreams;
    uint16_t sinit_max_ostreams;
    uint16_t sinit_max_attempts;
    uint16_t sinit_max_init_timeo;
}

```

If this socket option is used to set values, it must be done before an association is made. The parameters will be sent to the peer end-

point during association initialisation.

Each endpoint in an association will have an idea of how many input and output streams it will allow on an association, as discussed in the previous paragraph. During the establishment of the association, the endpoints exchange these values. Negotiation of final values is just a matter of taking the minimum values. If one end wants 20 output streams, and the other wants only 10 input streams, the result is the smaller, 10, and similarly for the number of streams in the opposite direction.

```

An endpoint will need to know how many output streams are available for writing in order not to exceed the limits. This value is determined during association setup. After setup, the endpoint can find this by making a query using `getsockopt()`. However, there is a little wrinkle here: a socket may have many associations (to different endpoints), and each association may have set different values. So, we have to make a query that asks for the parameters for a particular association, not just for the socket. The parameter to ask for is `SCTP_STATUS`, which takes a structure of type `sctp_status`:

```
struct sctp_status {
```

```

    sctp_assoc_t    sstat_assoc_id;
    int32_t         sstat_state;
    uint32_t        sstat_rwnd;
    uint16_t        sstat_unackdata;
    uint16_t        sstat_penddata;
    uint16_t        sstat_instrms;
    uint16_t        sstat_outstrms;
    uint32_t        sstat_fragmentation_point;
    struct sctp_paddrinfo sstat_primary;
};

```

```
};
```

This has fields `sstat_instrms` and `sstat_outstrms`, which contain

```

if (client_sockfd == -1) {
    perror(NULL); continue;
}

memset(&status, 0, sizeof(status));
len = sizeof(status);
status.sstat_assoc_id = 0;

if (getsockopt(client_sockfd, IPPROTO_SCTP,
               SCTP_STATUS, &status, &len) == -1) {
    perror("get sock opt\n");
}

printf("Got: input streams: %d, output streams: %d\n",
       status.sstat_instrms,
       status.sstat_outstrms);

for(;;) {
    /* transfer data */
    len = sizeof(client_addr);
    bzero(&sinfo, sizeof(sinfo));
    nread = sctp_recvmmsg(client_sockfd, buf, SIZE,
                          (struct sockaddr *) &client_addr, &len,
                          &sinfo, &flags);

    if (nread == 0) {
        break;
    }

    printf("read %d bytes on channel %hd\n", nread,
           sinfo.sinfo_stream);
    printf("sinfo flags: %d\n", sinfo.sinfo_flags);
    write(1, buf, nread);
}
close(client_sockfd);
}
}

```

the required information. See Listings 2 and 3 for a client and server negotiating the number of streams in each direction.

Association ID

For the one-to-one socket we discussed in the first article in this series, there can be only one association at any time. For the one-to-many sockets we will cover in the next article, there can be many associations active at any one time—a peer can be connected to many other peers simultaneously. This is different from TCP where only one connection on a socket can exist and also is different from UDP where no connections exist and messages are just sent to arbitrary peers.

When there can be many associations, you need to be able to distinguish between them. This is done by an opaque data type called an association ID. You need to use this sometimes, but not every time. For one-to-one sockets, there is only one association, so the association ID is always ignored. For one-to-many sockets, when the association is “obvious”, the association ID again is ignored. This occurs, for example, when you write to a peer and give the peer’s socket address; there can be only one association to a peer (but many associations to many peers), so if the peer is known, the association is known, and there is no need for the ID. But the association ID has to be used when the SCTP stack cannot work out for itself which association is meant. One place where this happens is in the `getsockopt()` call described previously to find the number of streams of an association on a one-to-many socket. I will defer the discussion of how to find the association ID to the next article, where I look at one-to-many sockets.

Writing to and Reading from a Stream

There are several ways of writing to a stream and telling to which stream a read belongs. Some of them make use of a structure of type `sctp_sndrcvinfo`:

```
struct sctp_sndrcvinfo {
    uint16_t sinfo_stream;
    uint16_t sinfo_ssn;
    uint16_t sinfo_flags;
    uint32_t sinfo_ppid;
    uint32_t sinfo_context;
    uint32_t sinfo_timetolive;
    uint32_t sinfo_tsn;
    uint32_t sinfo_cumtsn;
    sctp_assoc_t sinfo_assoc_id;
}
```

Most of the fields in this structure are not of interest to us at the moment. The interesting one is the first one, `sinfo_stream`. To write to a particular stream, zero out all fields and set this one; to read, zero out all fields again, do the read, and then examine this field. (As an aside, if the SCTP stack cannot work out which association is meant, the last field, `sinfo_assoc_id`, must be set.)

The function call to write a message is:

```
int sctp_send(int sd,
             const void *msg,
             size_t len,
             const struct sctp_sndrcvinfo *sinfo,
             int flags);
```

where the field `sinfo_stream` of `sinfo` has been set.

The call to read is, conversely:

```
ssize_t sctp_rcvmsg(int sd,
                  void *msg,
                  size_t len,
                  struct sockaddr *from,
                  socklen_t *fromlen,
                  struct sctp_sndrcvinfo *sinfo
```

```
int *msg_flags)
```

The stream number is then available in `sinfo.sinfo_stream`.

The SCTP stack keeps a lot of information about each message that passes between peers. It also keeps information about the state of each association. To avoid overloading applications, most of this information is suppressed and is not passed to the application. In particular, by default, the structure `sctp_sndrcvinfo` is not filled in, so a reader cannot tell on which stream a read occurred! To enable this to be filled, a socket option must be called first as:

```
struct sctp_event_subscribe events;
bzero(&events, sizeof(events));
events.sctp_data_io_event = 1;
setsockopt(sockfd, IPPROTO_SCTP,
          SCTP_EVENTS, &events, sizeof(events));
```

(More details on SCTP events will be given in the next article.) See Listings 4 (`streamsend_echo_client.c`) and 5 (`streamsend_echo_server.c`) for an example of a client and server using a specific stream for communication.

There is no way to specify from which stream to read. This is deliberate; the intention is that when data is ready on any stream, then you read it. Otherwise, data could be blocked on a stream with no one to read it, which eventually could fill up system buffers. So, you can’t restrict reading to any particular stream. But, once a read is done, you can tell which stream it has come from by using the mechanism above.

Typically, a server that reads and handles a message will have (pseudocode) that looks like this:

```
while (true) {
    nread = sctp_rcvmsg(..., msg, ..., &sinfo, ...)
    if (nread <= 0) break;
    assoc_id = sinfo.sinfo_assoc_id;
    stream = sinfo.sinfo_stream;
    handle_mesg(assoc_id, stream, msg, nread);
}
```

This is a single-threaded read loop. It ensures that information is read, no matter what association or stream it is sent on. The application function `handle_mesg()` can, of course, dispatch the message to different threads if it wants. Writes, on the other hand can be sent from multiple threads if desired.

Conclusion

This article has discussed a feature novel to SCTP, streams. A stream allows multiple data channels on a single association. This avoids a major problem of TCP, head-of-line blocking, but it also allows applications that deal with multiple logical streams to be written more easily. The next and final article will look at how SCTP can handle multiple associations at once, simplifying the TCP model and also offering improvements over the UDP connection model. ■

Reno-Sparks
Convention Center
Reno, Nevada

November 10-16, 2007

SC07, the premier international conference on high performance computing, networking, storage, and analysis, will convene in November 2007 in Reno, Nevada. SC07 expands the frontiers of those high performance technologies with a new initiative in high performance clusters. Of course, SC07 will also host the exceptional technical program, tutorials, workshops, exhibits, education program, and other exciting activities you've come to expect with the SC conferences.

SC is the one place attendees can see tomorrow's technology being used to solve world-class challenge problems today. This series has become a unique gathering spot for international scientists, researchers, software developers, network engineers, policy makers, corporate managers, CIOs, and IT administrators. SC07 represents the latest and greatest in technology, applications, industrial products, research results, and national/international initiatives. *We look forward to your participation!*

Conference Location:
Reno, Nevada

Conference Dates:
November 10-16, 2007

Exhibition Dates:
November 13-15, 2007

Multimedia Dynamite

An overview of the awesome power and configurability of MPlayer. GIRISH VENKATACHALAM

What should the Linux movie player of your dreams do? It should play any movie/video that you throw at it. No questions asked—just play. It should allow seeking and volume control with the keyboard and mouse. It should work with an infrared remote controller and also play television. It should play DVDs and VCDs too. MPlayer can do all of this and much, much more.

MPlayer also is an award-winning, mature, open-source program that still is actively in development. Perhaps one day in the not-too-distant future, support for DVD menus, color subtitles, picture in picture video, MIDI and audio effects plugins like the ones for SoX will be added.

MPlayer is admirably stable for the job it does. However, it does crash under certain circumstances, such as with certain video drivers.

It is a mature application that has no parallel. MEncoder, its companion video encoder program, does a much better job than FFmpeg in transcoding videos, although it is a bit difficult to use and learn.

Now, let's take a look at MPlayer's magic. The following command plays a stream URL after resampling it to 48,000Hz and combining channels into left-right stereo:

```
$ mplayer -af lavcresample=48000,rtf
↳ 'http://mp3.streampower.be/radio1-mid.mp3'
```

The following command grabs the same URL stream and dumps it to a file named stream.aac:

```
$ mplayer -dumpstream -dumpfile stream.aac
↳ -softvol -softvol-max 2000 -af
↳ lavcresample=48000,volnorm=2:0.5
↳ 'http://mp3.streampower.be/radio1-mid.mp3'
```

You can open the stream file from another terminal window with this command:

```
$ mplayer stream.aac
```

Then what happens? The first instance of MPlayer continues to dump the network stream to a file and the second plays it for you—time-shifted Internet radio. Cool, eh?

Most of the switches are not necessary to accomplish this, but they show MPlayer's ability to use the Linux command line so elegantly. The `-softvol` and `-softvol-max` switches invoke the software volume control feature of MPlayer. It reduces the signal-to-noise ratio, but it can amplify the signal to very high levels.

The `volnorm=2:0.5` filter invokes the volume normalization audio filter. The first argument, 2, specifies that several samples are to be used to smooth the volume variations. The 0.5 sets the maximum amplitude to which you want the volume normalized. As you can see, MPlayer provides a high level of customization.

The other options on the command line should not be difficult to decipher.

Playlists

The following is a command similar to the first one above. In this case, however, you specify a playlist URL. Unlike the above command, this one may not work for you, depending on whether the file happens to be available from the SHOUTcast site when you try it:

```
$ mplayer -af lavcresample=48000,rtf -playlist
↳ 'http://www.shoutcast.com/sbin/shoutcast-playlist.pls?rn
↳ =1025&file=filename.pls'
```

The `-playlist` option is used only with stream URLs that have a `.pls` extension in the stream.

You can create your own playlists in a variety of ways. Here is one way to do it with the `find` command:

```
$ find /home/girish/music -name "*.mp3"
↳ -or -name "*.ogg" > ~/playlist.txt
```

Now, fire up MPlayer with:

```
$ mplayer -playlist ~/playlist.txt
```

The following variant shuffles the list and plays songs in random order without repeating songs:

```
$ mplayer -shuffle -playlist ~/playlist.txt
```

Naturally, MPlayer is a media player. You don't have to limit yourself to audio files. You could add any MPlayer-playable media file into the mix, including videos, movies, television, radio and, of course, Internet streams.

In addition to this simple line-based playlist format, MPlayer also has excellent support for ASX, M3U and other popular playlist formats.

Special Effects

There is good support for audio effects, and the karaoke effect especially gets interesting with certain songs. It is not perfect, but you can attenuate the voice in a song a great deal. Use the following command to activate karaoke mode:

```
$ mplayer -af karaoke song.mp3
```

MPlayer also has a ten-octave band equalizer. The following command ignores the middle frequency bands and amplifies the frequencies around 31.25Hz by 7dB, 62.5Hz by 8dB, 125Hz by 5dB and all of the frequencies around 4, 8 and 16Hz are attenuated by 2dB:

```
$ mplayer -af equalizer=7:8:5:0:0:-2:-2:-2 video.mp3
```

The following command gives a live effect to playback. Try it with songs that sound monotonous:

```
$ mplayer -af extrastereo song.mp3
```

You can issue a command like the following to play the third song five times:

```
$ mplayer song1.mp3 song2.ogg file.wav -loop 5
```

If you want to repeat the whole list five times, type the following instead:

```
$ mplayer { song1.mp3 song2.ogg file.wav } -loop 5
```

You also can use `-loop 0` to play something over and over again. Additionally, there are many audio effect plugins designed especially for multichannel and 3-D audio. If you want some really advanced audio effects, try the SoX Swiss Army knife. It is another command-line application that excels in professional audio effects. You can specify multiple audio filters on the command line and they are applied one after another in a chain.

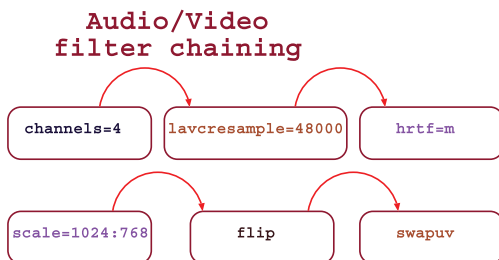

Figure 1. MPlayer Audio/Video Filter Chaining

What if you like a certain audio filter chain and you want to save the resulting audio to a file? The following command saves the output of filtering to the file named `filtered.wav` rather than playing it:

```
$ mplayer -ao pcm:file=filtered.wav -channels 4 -af lavcresample=48000,hrtf,pan=2:1:0:0:0.3:0.5:0.5:0:12 audio.ogg
```

The `lavcresample` filter resamples the frequency of `audio.ogg` to 48,000Hz.

The `pan` filter is a very powerful and sophisticated filter. It mixes the input audio channels into the specified output channels in various amplitudes.

In this example, we use the `-channels` switch to specify four input channels. The first argument to `pan` is 2 to specify two output channels. In the first pair of arguments after that, the 1:0 specifies the amplitude of the first input channel that is fed into the two output channels. It goes into the left channel with an

Figure 2. MPlayer with Basic OSD Support

Figure 3. MPlayer OSD Menu

Figure 4. MPlayer Built-in Console

amplification factor of 1. The second input channel goes into the right channel with an amplification factor of 0.3 (0:0.3), and the third input channel is divided equally into both output channels (0.5:0.5). The fourth channel goes into the right channel with an amplification factor of 12.

You can use the following command to re-encode the WAV file to Ogg:

```
$ oggenc -q 9 filtered.wav
```

The Command Subsystem

MPlayer has a very rich input command processing subsystem that can be manipulated with the keyboard, mouse, joystick or LIRC remote control. You also can customize several keyboard keys to invoke MPlayer's controls.

The following provides the list of keys that can be configured. The defaults are very sensible, and you may not need to change them:

```
$ mplayer -input keylist
```

You also can find MPlayer's controls for seeking, volume control, brightness correction and other things with the following command:

```
$ mplayer -input cmdlist
```

The `slave.txt` file that comes with MPlayer's documentation explains how to customize the `input.conf` and `menu.conf` files that come with the MPlayer package in your Linux distribution.

You also can have MPlayer accept input commands from a FIFO file (FIFO stands for First In, First Out). This comes in handy when it is reading the media from the standard input:

```
$ mkfifo /tmp/fifo
$ cat playlist.txt | mplayer -input
  file:/tmp/fifo -cache 8192 -playlist -
```

Typing the following mutes and executes it again with the

Figure 5. MPlayer with OSD of Media File Information

audio unmuted:

```
$ echo 'mute' > /tmp/fifo
```

You can use the mouse for the usual seek operations. The mouse wheel is configured by default to seek files in both directions.

On-Screen Display

Apropos of input methods, MPlayer has excellent support for on-screen display (OSD). I normally use only the superb scalable TTF fonts. These are not available on the MPlayer Web site.

The following command displays a timer:

```
$ mplayer -osdlevel 3 -font  
~/home/girish/.ttffonts/Comicbd.ttf video.avi
```

See Figure 2 for a sample of this display.

You can create a custom menu to browse using the keyboard with the OSD facility. It even has a console where you can enter MPlayer slave commands.

As you can see, the scalability of the OSD fonts does not break with the video scale filter.

Here is how to create this kind of configuration. First, set up most

everything in the config file. Here is my ~/.mplayer/config file:

```
# Write your default config options here!  
# Use Matrox driver by default.  
vo=sdl  
font=/home/girish/.ttffonts/comicbd.ttf  
vf=hue,eq,screenshot  
#menu-startup=yes  
menu=yes  
subfont-autoscale=3  
subfont-osd-scale=8  
subfont-text-scale=8  
subpos=50  
spuaa=4  
osdlevel=3  
# I love doing headstand (Sirsasana) while watching videos.  
#flip=yes  
# Decode/encode multiple files from PNG.  
# start with mf://filemask  
mf=type=png:fps=25  
# Eerie negative images are cool.  
#vf=eq2=1.0:-0.8
```

LINUX
JOURNAL™

Since 1994: The Original Monthly Magazine of the Linux Community

Subscribe today at www.linuxjournal.com

The input configuration and menu configuration are stored separately in `input.conf` and `menu.conf`, respectively. The `menu.conf` file needs to have a section that looks something like this:

```
<cmdlist name="main" title="MPlayer OSD menu" ptr="<>" >
  <e name="Pause" ok="pause"/>
  <e name="Prev/Next" ok="pt_step 1" cancel="pt_step -1"/>
  <e name="Jump to ..." ok="set_menu jump_to"/>
  <e name="Open ..." ok="set_menu open_file"/>
  <e name="Open playlist ..." ok="set_menu open_list"/>
  <e name="Help" ok="set_menu man"/>
  <e name="Pref" ok="set_menu pref_main"/>
  <e name="Properties" ok="set_menu properties"/>
  <e name="Console" ok="set_menu console0"/>
  <e name="Quit" ok="quit"/>
</cmdlist>
```

You need this line in `input.conf` in order to tell MPlayer what event invokes the menu. The setting here invokes the menu if you click the left-mouse button:

```
MOUSE_BTN0 menu main
```

Custom Subtitles

Not surprisingly, MPlayer understands close to 12 subtitle formats, and it has its own MPSub format too. The options for subtitle display are the richest I have seen. You can display subtitles in any size, any position on the video, move them dynamically with the keyboard, adjust the delay, change the transparency, format them into multiple lines and so on.

Here is the most basic usage of the file `subtitles.txt`:

```
FORMAT=TIME
# first number : wait this much after
# previous subtitle disappeared
# second number : display the current
# subtitle for this many seconds

2 3
What is going on?

4 3
How are you doing?

8 3
You are wrong!

0 3
A long long, time ago...
in a galaxy far away...

0 3
Naboo was under an attack.

0 200
I don't understand this.
```

Tell MPlayer to use this file with a command like this:

```
$ mplayer -sub subtitles.txt  
  -font ~/.ttffonts/Verdana.ttf video.avi
```

This next command dumps the subtitles file into the srt format into the file `dumpsrt.sub` in the current directory:

```
$ mplayer -sub subtitles.txt video.avi  
  -dumpsrtsub
```

You can take a quick look at all subtitles in the file by pressing the Y and G keys. Of course, you can specify multiple subtitle files, and you can switch between them.

Create Screenshots

Want to take screenshots with MPlayer? It's easy. Here's a sample command to use when you start to play a video:

```
$ mplayer -vf screenshot video.avi
```

Press S when you want to take a screenshot. If you want a screenshot every five seconds, try the following command:

```
$ mplayer -vo png -vf screenshot -sstep 5  
  -video.avi
```

What if you want to take a screenshot of every frame? Set MPlayer to accept slave commands with a FIFO, and type these commands:

```
$ mkfifo /tmp/fifo  
$ mplayer -input file:/tmp/fifo video.mpg  
$ echo 'screenshot 1' > /tmp/fifo
```

Toggle the screenshot process with the following command while the video is playing:

```
$ echo 'screenshot 1' > /tmp/fifo
```

You might want to use the `-vf spp,scale=1024:768` switch to get full-screen screenshots.

Even More Power

There's much more MPlayer can do. You can encode image files into a video and extract frames into image files with MPlayer. You also can watch analog television with the `tv://` option and watch

DVB channels with the `dvb://` option. It supports a wide variety of streaming protocols, including RTP, RTSP, MMS, SDP and LIVE5555 streaming.

Discover the Power Yourself

The following command lists the available filters:

```
$ mplayer -af help
```

The man page and MPlayer's HTML documentation have more thorough descriptions of its options. Typing:

```
$ mplayer -vo help
```

lists the compiled video output drivers.

You can play an arbitrary audio file with the video using:

```
$ mplayer video.mpg -audiofile audio.aac
```

Of course, MPlayer can play a wide variety of audio and video media files. The following commands list them:

```
$ mplayer -vo help
```

```
$ mplayer -ao help
```

Try using the `-audio-demuxer` switch along with `-rawaudio`.

I hope this gets you started in discovering the awesome power of MPlayer. Enjoy your multimedia experience! ■

FS-Cache and FUSE for Media Playback QoS

Use FS-Cache to remove fluctuating performance issues from media playback. **BEN MARTIN**

The **FS-Cache Project** works with network filesystems like NFS to maintain a local on-disk cache of network files. The project is split into a kernel module (`fscache`) and a daemon (`cachefilesd`), which help to maintain the disk cache. The local on-disk cache is maintained under a directory on a local filesystem. For example, the `/var/fscache` directory on the ext3 filesystem `/var`. The filesystem containing the `fscache` directory must have the ability to use Extended Attributes (EAs). Such filesystems are quite common and include ext3 and xfs.

Early Fedora Core 6 kernel RPMs contained the `fscache` kernel module. Unfortunately, around version 2.6.18-1.2868.fc6 of the updated kernels, the module was no longer included. Fedora 7 kernels do not include the kernel module. Hopefully in the future, this module will be available again in standard Fedora kernels. The Fedora Core 6 update kernel 2.6.20-1.2948.fc6 has an FS-Cache patch included, but it does not include the kernel module.

Patches are available for the Linux kernel for the FS-Cache kernel module (see Resources).

The `cachefilesd` daemon communicates with the kernel module using either a file in `/proc (/proc/fs/cachefiles)` or a device file (`/dev/cachefiles`). Version 0.7 and earlier versions of `cachefilesd` could communicate only via the `proc` file; Version 0.8 also can use the device file if it is available with fallback to the `proc` file.

Setting Up `cachefilesd`

For Fedora Core 6 and Fedora 7, there is a `cachefilesd` RPM. Installation without package management should be fairly easy also, as the daemon mainly consists of a single executable and a configuration file (`/etc/cachefilesd.conf`).

The two main things that need to be set up in the configuration file are the path of the directory to use under which to store the filesystem cache and options for controlling how much space is acceptable to use on the filesystem containing the cache directory. You also can supply a tag for the cache if you want to have multiple local disk caches operating at the same time.

The space constraints all have acceptable defaults, so the cache directory is the only configuration option you need to pay attention to. Make sure that this directory is acceptable for storing caches and that it exists prior to trying to start `cachefilesd`. For a media PC, using a directory on a Flash memory card or on a RAM disk is a good option.

Because the cache directory must have extended attributes, and your `tmpfs` might not include support for them, you may have to create an ext3 filesystem in a single file inside your `tmpfs` filesystem and then use the embedded ext3 filesystem for the `cachefilesd` path. The ext3 filesystem inside the single file happily will support extended attributes. Because the whole ext3 filesystem is in a single file on a RAM disk, it will not cause distracting disk IO on the media PC.

The `fstab` entry in Listing 1 sets up both a 64MB of RAM filesystem and the mountpoint for the embedded ext3 filesystem. The commands

shown in Listing 2 set up the embedded ext3 filesystem. As the `cache.ext3fs` filesystem exists only in RAM, you have to add these commands to your `/etc/rc.local` or a suitable boot-time script to set up the cache directory after a reboot. This script has to be called before `cachefilesd` is started. Leaving `cachefilesd` out of your standard init run-level startups and starting it manually from the `rc.local` just after you set up the `cache.ext3fs` embedded filesystem is a good solution.

If the cache directory is on a persistent filesystem, such as `/var`, set `cachefilesd` to start automatically, as shown in Listing 3.

The space constraints in the configuration file are used to set the percentage of available blocks and files on the filesystem containing the local cache directory that should be used. For each of these two resource types, there are three thresholds: `cull-off`, `cull-start` and `cache-off`. When the `cull-off` limit is reached, no culling of the disk cache is performed, and when the `cull-start` limit is reached, culling of the disk cache begins. For example, for the disk block type constraint, setting `cull-off` at 20% and `cull-start` at 10% means that as long as the disk has more than 20% free blocks, nothing from the cache will be culled. Once the disk reaches 10% free blocks, cache culling begins to free up some space. If the disk manages to get to the `cache-off` limit (say, 5%), the cache will be disabled until there is more `cache-off` space available again.

Listing 1. Using a RAM Disk to Store the Local `fscache` On-Disk Cache

```
tmpfs /var/fscache tmpfs size=64m,user,user_xattr 0 0
/var/fscache/cache.ext3fs /var/fscache/cache
➔ext3 loop=/dev/loop1,user_xattr,noauto 0 0
```

Listing 2. Setting Up the Embedded ext3 Filesystem

```
# mount /var/fscache
# cd /var/fscache
# dd if=/dev/zero of=cache.ext3fs \
    bs=1024 count=65536
# mkfs.ext3 -F cache.ext3fs
# mount cache.ext3fs
```

Listing 3. Starting the `cachefilesd` Daemon and Setting It to Auto-Start Next Boot

```
$ su -l
# service cachefilesd start
# chkconfig cachefilesd on
```

The configuration options are prefixed with `b` for block type constraint and `f` for the files-available constraint. The configuration file has a slightly different naming method from that used above. For block constraints, the cull-off limit is called `brun`. For cull-start, the limit is called `bcull`, and cache-off is called `bstop`.

Modifying Mounts

To turn on FS-Cache for a mountpoint, you have to pass it the `fsc` mount option. I noticed that I had to enable FS-Cache for all mountpoints for a given NFS server, or FS-Cache would not maintain its cache. This should not be much of an issue for a machine being used as a media PC, because you likely will not mind having all NFS mounts from the file server being cached.

The `fstab` entry shown in Listing 4 includes the `fsc` option. Adding this `fsc` option to all mountpoint references to `fileservers:/...` will enable FS-Cache.

Listing 4. `fstab` Entry for Mounting an NFS Directory on the Fileserver with FS-Cache

```
fileservers:/foo /foo nfs bg,intr,soft,fsc 0 0
```

Preemptive Caching

At this stage, FS-Cache will store a local cache copy of files, or part thereof, which is read off the file server. What we really want is to have data from files we are viewing on the media PC to be read ahead into the local disk cache.

To get information into the local disk cache, we can use a FUSE module as a shim between the NFS mountpoint and the application viewing the media. With FUSE, you can write a filesystem as an application in the user address space and access it through the Linux kernel just like any other filesystem. To keep things simple, I refer to the application that provides a FUSE filesystem simply as a FUSE module.

The FUSE filesystem should take the path to the NFS filesystem we want to cache (the delegate) and a mountpoint where the FUSE filesystem is exposed by the kernel. For example, if we have a `/HomeMovies` NFS mount where we store all our digital home movies, the FUSE module might be mounted on `/CacheHomeMovies` and will take the path `/HomeMovies` as the delegate path.

When `/CacheHomeMovies` is read, the FUSE module will read the delegate (`/HomeMovies`) and show the same directory contents. When the file `/CacheHomeMovies/venice-2001.dv` is read, the FUSE module reads the information from `/HomeMovies/venice-2001.dv` and returns that. Effectively, `/CacheHomeMovies` will appear just the same as `/HomeMovies` to an application.

At this stage, we have not gained anything over using `/HomeMovies` directly. However, in the `read(2)` implementation of the FUSE module, we could just as easily ask the delegate (`/HomeMovies`) to read in what the application requested and the next 4MB of data. The FUSE module could just throw away that extra information. The mere act of the FUSE module reading the 4MB of data will trigger FS-Cache to read it over the network and store it in the local disk cache.

The main advantage of using FUSE is to allow caching to work properly when the video playback is sought. The main disadvantage is the extra local copying where the FUSE module asks for more information

than is returned to the video player. This can be mitigated by having the FUSE module request only the extra information every now and then—for example, reading ahead only when 2MB of data has been consumed by the application.

For optimal performance, the read-ahead should happen either in a separate thread of control in the FUSE module and use `readahead(2)` or asynchronous IO, so that the video playback application is not blocked waiting for a large read-ahead request to complete.

The FUSE Shim

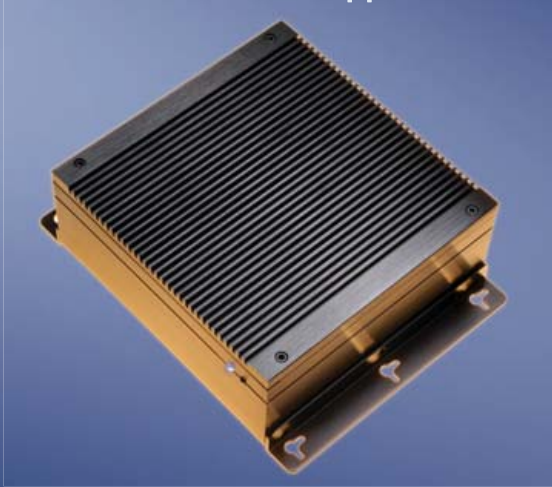

The `fuselagefs` package is a C++ wrapper for FUSE. It includes the `Delegatefs` superclass, which provides support for implementing FUSE modules that take a delegate filesystem and add some additional functionality. The `Delegatefs` is a perfect starting point for writing simple shim filesystems like the above `nfs-readahead` FUSE module.

The read-ahead algorithm is designed to read 8MB using asynchronous IO, and when the first 4MB of that is shown to the application using the FUSE filesystem, it then reads another 8MB using asynchronous IO. So there should be, at worst, 4MB of cached data always available to the FUSE module.

The C++ class to implement the shim is about 70 lines of code, as shown in Listing 5. Two offsets are declared to keep track of what the file offset was in the previous call to `fs_read()` and at what offset we should launch another asynchronous read-ahead call. The `aio_buffer_sz`

LOGIC SUPPLY www.logicsupply.com

is declared constant as an enum so it can use it to declare the size of `aio_buffer`. When `aio_consume_window` bytes of the `aio_buffer` are shown to the application using the FUSE filesystem, another read ahead is performed. If `debug_readahead_aio` is true, the FUSE module explicitly waits for the asynchronous read-ahead to finish before returning.

This is handy when debugging to ensure that the return value of the asynchronous IO is valid. A non-illustrative example would have some callback report if an asynchronous IO operation has failed.

The main job of `schedule_readahead_aio()` is possibly to execute a single asynchronous read-ahead call. It updates `m_startNextAIOOffset` to tell

```

Listing 6. Makefile for the FUSE Shim

```
nfs-fuse-readahead-shim: nfs-fuse-readahead-shim.cpp
    g++ nfs-fuse-readahead-shim.cpp \
        -o nfs-fuse-readahead-shim \
        -D_FILE_OFFSET_BITS=64 -lfuse_lagefs
```

itself when the next asynchronous read-ahead call should be made. The `forceNewReadAhead` parameter allows the caller to force a new asynchronous read-ahead for cases such as when a seek has been performed.

The `fs_read()` method is a virtual method from `Delegatefs`. It has similar semantics to the `pread(2)` system call. Data should be read into a buffer of a given size at a nominated offset. The `fs_read()` method is called by FUSE indirectly. The main logic of our `fs_read()` is to check whether the given offset is in a logical sequence from the last read call. If the offset is not sequential from the last byte returned from the previous read(), `fs_read()` will force `schedule_readahead_aio()` to perform another read ahead. `schedule_readahead_aio()` is always called from `fs_read()` so it can handle the sliding asynchronous read-ahead window.

As `Delegatefs` knows how to read bytes from the `Delegate` filesystem, we then can simply return by calling up to the base class. The remainder of `nfs-fuse-readahead-shim.cpp` is taken up by parsing command-line options, and instead of returning from `main()`, it calls the main method of

a `Delegatefs` through an instance of the `CustomFilesystem` class. The shim is compiled with the Makefile shown in Listing 6.

Taking It for a Spin

A simple application that reads from a given file at a predetermined rate can verify that the cache is being populated as expected, as shown in Listing 7. There isn't a great deal of error checking going on, but things that would cause grief, such as failed read()s, are reported to the console. The application repeatedly reads 4KB chunks at a time from a nominated file and throws away the result. Every 256KB status is reported, so that the application can be closed knowing roughly what byte of the file was last read.

As shown in Listing 8, we first clean out the cache directory and restart `cache/filesd`. Then, the NFS share is mounted and the FUSE shim run against it to create a `/Cache-HomeMovies` directory. The FUSE executable is told to remain in the foreground, which stops FUSE from running it as a daemon, allowing standard output and standard error of the FUSE filesystem to be displayed. We use `bash` to put the `nfs-fuse-readahead-shim` into the background (though still having its standard outputs redirected into a capture file) and run the `simpleread` for a little more than 500KB of data. Then, both the `simpleread` and `nfs-fuse-readahead-shim` are stopped to investigate whether the cache has been populated as expected.

The `simpleread` was stopped after reading only a little more than half a

Listing 7. `simpleread.cpp` Reads from `argv[1]` at a Nominated usec Rate in `argv[2]`

```
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <errno.h>

#include <iostream>
#include <sstream>
using namespace std;

int main( int argc, char** argv )
{
    cerr << "opening argv[1]:" << argv[1] << endl;

    long offset = 0;
    int fd = open( argv[1], O_RDONLY );

    unsigned long usec = 10000;
    if( argc > 2 )
    {
        stringstream ss;
        ss << argv[2];
        ss >> usec;
    }
    cerr << "using delay of usec:" << usec << endl;

    const int bufsz = 4096;
    char buf[ bufsz ];
    bool error = false;
```

```
while( true )
{
    ssize_t rc = read( fd, buf, bufsz );
    if( rc > 0 )
    {
        if( error )
        {
            cerr << "reading resumed" << endl;
        }
        error = false;
        offset += rc;
    }
    else if( rc == 0 )
    {
        cerr << "end of file" << endl;
        exit(0);
    }
    else
    {
        error = true;
        cerr << "read error:" << errno
            << " at offset:" << offset
            << endl;
    }
    usleep( usec );
    if( offset % (1024*256) == 0 )
        cerr << "offset:" << offset << endl;
}
return 0;
}
```

megabyte. However, the FUSE module has an asynchronous IO call at the start, requesting 8MB of data be sent to it. Poking around in `/var/fscache` for a file with the same size as `venice-2001.dv` should reveal the cache file.

Listing 8. Running `simpleread` against the FUSE Shim

```
# rm -rf /var/fscache/*
# /etc/init.d/cache/filesd restart
# mount fileserver:/HomeMovies /HomeMovies -o fsc
# nfs-fuse-readahead-shim --fuse-forground \
  -u /HomeMovies /Cached-HomeMovies \
  >|/tmp/nfs-fuse-out 2>&1 \
  &

# simpleread /Cached-HomeMovies/venice-2001.dv 1000
using delay of usec:1000
offset:262144
offset:524288
^C
# fg
^C
#
```

Comparing the first 8MB of this cache file to the version on the NFS share should show that the first 8MB is identical. Note that the local cached file is read first to make sure that the subsequent use of the NFS share does not populate the cache file before it is read. This is shown in Listing 9.

Listing 9. Checking That the Cache Has Read the First 8MB

```
# cd /var/fscache
# ll -R
...
----- 1 root root 800M Jun 10 02:19 Ek0...000000
# dd if=./path/to/Ek0...000000 \
  of=/tmp/8mb bs=1024 count=8192
# dd if=/HomeMovies/venice-2001.dv \
  of=/tmp/8mb.real bs=1024 count=8192
# diff /tmp/8mb.real /tmp/8mb
#
```

Wrap-Up

One restriction on FS-Cache is that it will not cache files opened with `O_DIRECT` or for writing.

By taking advantage of the kernel FS-Cache code, the FUSE module to handle read-ahead can be very simple to create. The `Delegatefs C++` FUSE base class allows one to implement additional features very easily when applications perform IO.

The FUSE `nfs-fuse-readahead-shim` module is started just as shown in Listing 8 and when the `--fuse-forground` option is not passed, `nfs-fuse-readahead-shim` runs silently as a `dæmon`. ■

More Power to Linux

New digs means an opportunity for Linuxization of the home.

Nick Petreley, Editor in Chief

What a month. I'm thinking of changing my name to Nicholas Almighty in hope God will send me plans for an ark. This has been one of the rainiest years on record for south central Texas. The rain hasn't bothered me too much because the weather is still warm, but it seems as if anything more than a drizzle causes power and cable interruptions in my little section of San Antonio. I have potent power-surge protectors and a UPS (that stopped working recently, unfortunately), but the frequent power surges from having the power drop out repeatedly eventually fried my server, and then fried the RAID cage in the server after I fixed it. I didn't think the latter was possible, but I have no other explanation for why, immediately after one of the latest power outages, the RAID cage stopped recognizing one of the drives. I guess electronics is electronics, and anything can blow. My replacement cage arrived literally as I was typing this, so I should have a working server again soon.

I'm hoping that by the time you read this, I will have moved to a house in a small town just outside San Antonio. I don't know if the new location will solve my power problems or make them worse, but I do know it means I have to

give up cable, and along with it, Roadrunner. The only Internet access in this area is dial-up, satellite and wireless. I opted for wireless broadband, although I use the term "broadband" loosely, as we're talking about a maximum of about 800Kbps download speed. When I signed up, the fellow remarked that I was about the fourth Linux user he'd encountered this month. He confessed that he's not very familiar with Linux, although his company runs Linux on some servers.

He said there's a noticeable increase in Linux usage among his customers. That didn't surprise me, but his next comment did. He said he figures Linux is gaining some popularity because it's no longer a command-line-only operating system. Perhaps I shouldn't be surprised. Most computer users can remain blissfully ignorant of how long Linux has had superior graphical desktops, because they have something they consider to be good enough. Most of us are of the opinion that alternatives like Windows aren't good enough, because we've been feasting on steak for quite some time. We have a point of reference. They don't.

I have a feeling that Linux evangelism doesn't work very well for spreading the word that Linux is a viable desktop. The fact that Dell now preloads Linux on desktop machines works much better. People visit Dell for a variety of reasons. It gives Linux visible credibility to see it as an option for Dell machines. In fact, I can't help but wonder if Dell's decision to preload Linux had something to do with this fellow hearing more about Linux users.

One of the dedications in a Linux book I wrote credits Bill Gates and Steve Ballmer for promoting Linux by making Windows more undesirable with every release. Look for a big influx of Linux users if Microsoft turns a recent patent idea into reality. Microsoft wants to add insult to injury by making Office as undesirable as Windows. The idea is to

make its office applications (Word, Excel and so on) examine your documents and collect data about you, so that Microsoft can sell targeted advertising. I'm not sure where Microsoft expects to place the smart ads. Perhaps they'll appear in a window within its word processor and spreadsheet. If so, this puts a whole new spin on an old "clippy" talking paper-clip joke. Now, you'll get a custom ad like, "It looks like you're composing a suicide letter. May we interest you in Gillette razor blades? They're on special this week at your local Walgreens." I, for one, say go for it Microsoft. A rush to OpenOffice.org or any other alternative office suite would be nothing but good news for Linux.

Moving to a permanent residence means I can start thinking about a Linux-based home. The house is too small to do anything really fancy, but I can build a simple multimedia box that also controls a number of house functions like lights and the thermostat. Ideally, I'd like to use voice commands to control some things. It's too bad that so little work seems to be ongoing for Linux voice recognition. A cursory search turned up a list of projects, but most of them haven't been touched in years. Sphinx 4 (cmusphinx.org) looks like the only decent active project. If you know of any others, please share.

I'm also thinking of setting up a tiny recording studio in the garage for myself and my kids. The Rosegarden music editor and midi sequencer may not be as powerful as some of the Windows commercial products, but it's remarkably feature-rich. It certainly has enough power for our meager talents.

Regardless, I'm looking forward to whatever Linuxization I can do to my new home. Wish me luck, but if you say, "more power to you", I prefer it to be steady state, no surges. ■
